Hi Raphael,

You stand more chance of measuring the noise of the computer. The
problem with dipoles is they are not shielded from earth (and some
dishes suffer equally - by degree). Try it first with Jupiter, a
known and stable source, which should give you some basis for your
further experimentation.

Ian, it can be proven that reflected power waves exist. Ramo & Whinnery say they exist. Standing waves in a single source, single feedline, single load system cannot exist without reflected waves. The HP Application Note AN 95-1 defines the power in reflected waves. "|a2|^2 = Power reflected from the load." Saying something is a misconception is only an opinion that differs from a lot of expert opinions.

> That question has *no* correct answer - and this newsgroup is living
> proof that none can be found.

The answer has been found but most people think they already know everything there is to know. The answer is contained in the following example. The sources are signal generators with circulator loads (SGCL). The (50) or (150) subscript is the ohmic value of the circulator load resistor. The signal generators are phase-locked and can be turned on and off independently.

100W SGCL(50)--1WL 50 ohm feedline--+--1/2WL 150 ohm feedline--33.33W SGCL(150)
Pfwd1--> Pfwd2-->
<--Pref1 <--Pref2

Step 1: With the 100W SGCL(50) on and the 33.33W SGCL(150) off, the following conditions exist:

Pfwd1 = 100W, Pref1 = 25W, Pfwd2 = 75W, Pref2 = 0W

Step 2: Now turn on the 33.33W SGCL(150). At the instant the rearward-traveling signal reaches the impedance discontinuity, the following conditions exist at the discontinuity:

Pfwd1 = 100W, Pref1 = 0W, Pfwd2 = 133.33W, Pref2 = 33.33W

All anyone has to do is figure out what happened to Pref1 = 25W in Step 1 the instant the 33.33W arrived at the impedance discontinuity in Step 2. This is not a transient buildup condition. If we ignore any distortion in the 33.33W Pref2 wavefront, this is an immediate event and Pref1 is immediately canceled by an equal magnitude and opposite phase Pref2(1-|rho|^2) wavefront at the moment it first arrives.

A few pretty bright individuals are convinced that this is what happens. That's up from zero a couple of years ago. The problem

appears to be that most people will not take the time and effort
to take a close look and understand the above example.

Source record: 112364

Hi Group, I have a balun that I believe is fried. Silly me, I tried to load up my 20 meter dipole on 40 meters with my amplifier. There was a flicker on the SWR meter then the SWR shot up to infinity. I'm sure I zapped the balun, but am curious to know if there's a way to test one, other than by connecting it to another set of wires.

Also, I'd like to cut the thing open and see what's inside. It's one of the typical kind that's in a 1 3/4" PVC tube with end caps. Is it possible to cut these things open or are these things potted with some compond on the inside?

Thanks for any advice and 73 to all,

Source record: 112365

Sigh. I guess one more time. A mouse in the maze.

70.7 volt RMS voltage source, 50 ohm series resistor. Connect to an open
circuited, half wavelength transmission line. Put your magic lossless
Bird wattmeter in the line and measure the forward and reverse power:

Pf = 100 watts
Pr = 100 watts

The "transmitter" is perfectly matched to the line.
The "reflected power" is 100 watts.
The dissipation of the "transmitter" source impedance is zero. Not 100
watts. Not even one watt. Zero.

No, how can anyone possibly say that when the transmitter is matched,
the reflected power is absorbed by the transmitter?

Any number of other examples can easily be found. You'll find a few
others in the "Food For Thought" series available from
ftp://eznec.com/pub/food_for_thought/.

I'm firmly in agreement with Bill and Ian on this one.

Hi Jack,

Strength is often associated with potential (Volts being common here).

Force is more often associated with power (by virtue of Newton, Watts being common here).

oomph is what an old fart mutters as he stirs uncomfortably in his chair while avoiding a bench test of his mental gymnastics.

Hi Dave,

First connect a Dummy Load in place of the BalUn at the remote end of
the feedline and confirm 1:1.

If you can visually inspect the BalUn's guts, it should be a simple
matter to determine if it exhibits a wire opened by fusing current, or
by a shorted condition often attended by char or smoke - this may be
more dicey.

At the bench, terminate the BalUn with the load it expects to
transform (using a non-inductive resistor). Apply power and note SWR
(take care to not incinerate the resistor).

Agreed. I guess my point was that if BPL interference becomes a
nationwide problem, _lots_ of people in the US will boost their
transmitter power so that they can be heard - *and* they'll be limited
to working stations who can do likewise.

This leads to a rather nasty non-compromise - you'll be limited to
working a much smaller set of stations (e.g. few or no DX, no QRP),
you'll spend a lot more on equipment, *and* your neighbors (BPL-using
and otherwise) will be much more likely to experience harmful
interference.

Yep, radio waves and light are the same stuff (photons) just different frequencies. They are all part of the electromagnetic spectrum that extends from DC to gamma rays (and higher?)

Using particle physics to explain radiation from an antenna is easier to understand than fields, waves, and Maxwell's equations. It allows us to picture a tangible particle leaving the antenna. And lots of things are understood about photons.

I still find it strange that the savants and pundits will say what it
is NOT, but NOT what it IS.

Is one Ohm too much?

Is ten thousand Ohms too little?

Do anyone of you have a simple number that must exist as a physically
verifiable entity of a physical example commonly available to any Ham?

What is it that heats up in the presence of mismatch that all
manufacturers go to great length to protect against? Does it have to
be a carbon resistor to qualify? Which one? Why is it so hard to
quantify in the face of such firm agreement among you gentlemen? My
guess is that you would refuse to warrant your answer in the face of
catastrophic failure - evidence contrary to your opinions.

Sorry, but puzzles and enigmas do not answer the reality of heat and
heat does not arrive through the offices of some virtualized component
born of substituted theories of matching.

Well, at least one thing you guys succeeded :
made me go to the library and start reading.

An initial feeling I have is that equations and
formulas (Maxwell's and alike) do [describe]
these phenomena; however they do little to
[explain] their very nature. Hence, I guess
pretty soon I will dive into quantum physics
to look for some answers.

For example, I needed the Special Theory of
Relativity to get myself convinced of the intrinsic
reality(!) of the electric/magnetic field. And
this was tough, since is hard to comprehend
some form of physical existence without the
support of matter.

Cordially,

Nic.

A light bulb is a transducer? Amusing example of non mechanical
translation until you touch it, then the phonons exhibit that
mechanical transfer in the form of heat. Common experience as your
hand approached that opportunity would have revealed that fate through
radiation and that is neglecting another mechanical form of energy
transmission offered. That other form is convection.

You have not offered counter-examples, you simply ignore positive
examples. I've spent nearly 30 years in the field of Electro-Optics
with contracts as recent as this year. I've yet to see the trade
press or research commonly describe these items as "transducers."
That is not to say I would reject any such reference, but I would say
few are treading that path to attend a philosophical distinction that
is largely semantic.

Stick with antenna as transducer, it makes a fine metaphor.

Call it a simple example. I would assume in a real system multiple pulses are would be highly undesirable and eliminated by discharging the line at the end of the first pulse. Maybe I should have said 100W pulse generator with on output impedance of 0 or infinity, and a lousy dummy load. At a lower power you could hook up a 'scope to the middle of the line and see the multiple reflections.

Hi Tam,

I would call your Radar a faulty example.

The point of the matter is that real equipment exhibits real
dissipation of reflected power in the conventional expectation. Your
new example above anticipates this by forcing a failure of that
expectation through not matching the load.

Such problems that arise as a consequence were written up by NBS,
Hewlett-Packard and Steven Adams in the discussion of Mismatch
Uncertainty.

The fact that various pundits and savants have no actual value to
offer in substitution for the oft-repeated refrain "it a'in't 50Ohms"
is that any value offered would be immediately demonstrated as being
wrong through standard bench top verification.

As Ian has characterized this as an exercise in futility, I am content
to observe no one stepping up to the bench for validation.

If the sig gen is putting out 100 watts, with 3 watts reflected and 97 watts going to the load, then 3 watts must be going to the circulator. If 100 watts is going to the load and 3 watts is reflected back to the circulator, then the sig gen is putting out 103 watts. But if 97 watts is getting to the load, 3 watts is reflected and there is no circulator or other load, then how much do you think the sig gen is actually putting out?

Yeah, seems to be a deep dark secret. If you look at the specs of RF power transistors, they will give the output impedance vs frequency - BUT you have to look at the footnote. In virtually all cases what they mean is the conjugate of the load impedance. It is the jX of the transistor (1/jY), in parallel with
((VCC-Vsat)**2) /2P.

I have never gotten around to doing this, but I believe the data sheets for tubes like the 811A and 813 do give the plate resistance, which should make it possible to calculate the output impedance at the lower frequencies like 160m.

Roy,

You are cheating. In the steady state there is no load on your source.
Regardless of what the Bird meter reads. Do one of the following:

1.Short the end of the 1/2 wave line.
2.Use a 1/4 wave open ended line.
3.Get a pulse generator, 0 Ohm output impedance +50 Ohm series resistor. Set the pulse with to 100ns and 1V, and use an arbitrary length of coax, either open or shorted, but longer than 100ns. Grab a 'scope and look at the junction of the coax and the 50 Ohm resistor. You will be able to see the .5V reflected pulse appear across the 50 ohm resistor. ALL of the reflected energy was absorbed, and half of the forward power.

==========

Of what use is the ARRL Antenna Book if the enquirer hasn't got it? If he had it he wouldn't be enquiring.

Anyway, if you have correctly quoted it, the ARRL Antenna Book is wrong,

Really Cec, ii's not like you to disseminate false information like some disreputable organisations we have recently become familiar with. Note the smiley ..... ;o)

Suggestion - to find a better value at HF why not use an Autek or MFJ antenna analyser.

Yours, Reg.

Hi Tam,

Motorola offers quite specific characteristics across frequency.
Reference MRF421, MRF433, MRF454 for examples of dirt ordinary power
transistors found in more than 20 years of transistorized Ham
transmitters. Take their own data, Z transform them through
transformers (not transducers) and you find 50Ohms without any more
sophisticated math than that required of the standard Technology
Certificate of training. Where does it go through after that? A low
pass filter designed for 50Ohms to an antenna jack specified to
deliver full power to a 50Ohm load.

What technical rebuttal do I hear in response to simple engineering
data? "It is impossible to determine the output Z of this source."
For some I can well imagine they do find it difficult....

Well, if you agree that two antennas/transducers in close
proximity will make a transformer (albeit a somewhat inefficient
one!), then i don't think i was that far off base.

You have convinced me that you are correct about both of these points.

But i don't think that an antennas impedance will not be affected by the permeability of the medium that surrounds it. An antennas input impedance will be different in free space as opposed to being immersed in water, for example.

This indicates to me that the antenna is indeed "matching" 50 Ohms to the impedance of free space, even if it is a different type of impedance.

Do you think that the characteristics of a transformer of a specific turns ratio, gauge wire, and core geometry, will NOT depend on the core material? I would say definitely it WILL depend on the material.

Actually, several people (W8JI among them) have measured the output impedance of common amateur linear amplifiers by at least a couple of methods. The most credible measurements show, interestingly, a value very close to 50 ohms when the amplifier is adjusted for normal operation.

Of course, it doesn't really matter, but people continue to make a big deal out of it.

Why is this cheating? There is reverse power on the line. The source is not absorbing the reverse power. You and others have said, without qualification, that it does. I've shown a case where it doesn't.

When talking of amateurs and transmitters, we're dealing with sinusoidal, steady state conditions. You've just described a transient pulse situation. It's different in several ways, one of the most important being that the source is off when the returning pulse arrives. I'm fully able to discuss TDR phenomena, but it's not relevant, and only adds confusion to a discussion of amateur transmitters and transmission lines.

In sinusoidal, steady state conditions, it's absolutely incorrect to say that the reflected power is absorbed by the source, whether the source is matched or not. And it's easy to show it's incorrect, as I've done.

Actually, an adequate core shouldn't appear as a significant factor in
transformer performance. Naturally, an inadequate core will adversely
affect it. But I just don't accept that as evidence, let alone "proof"
that an antenna is fundamentally an impedance matching device.

I see that you won't be swayed from your visualization. But hopefully
some of the other readers can see the fallacy of the concept. I think
I've done all I can, so I'll leave this topic now.

Chuckle I was just reminded of something that happened years ago, when
my son was a small boy. He learned that I was an engineer, so he
couldn't wait to see the train I drove. After a great deal of repeated,
patient, explanation, I finally got across (I thought) a description of
what I did, and that it had nothing to do with trains. Well, he had
occasion to visit me at work quite a long time later. He kept wandering
off. When I asked why, he explained that he was trying to find where the

train was kept. Yeah, I might not drive trains, but I must have *something* to do with trains.

Slick, you've got the right concepts now, but you're still looking for that train.

That table is just a lot of bullshit, those figures are completely
useless and far away from truth...
I wonder why you post this useless info into 5 newsgroups without
verifying the figures.
Are you paid by diamond?

By the way, your menu is still not visible with netscape navigator...

Apples and oranges? The levelling system has no direct effect on
phase response, input impedance or linearity, and in general not the
same effect on some of the others as you'll have in a linear feedback
control system.

You're sourcing and sinking an additional 33.33 watts, and yet the
wattmeter can't discern the difference between this scenario and the 100
watt, single source scenario.

The example illustrates perfectly the shortcomings of the idea of power
flow, as well as some of the faulty conclusions that can be drawn from
measurements made by a directional power meter.

Texas just had a hurricaine, albeit a fairly normal one.
The station at DPS in Austin was severly limited due to noise in their end.
Why do I point this out?
The noise levels in citites on HF are already so high as to endanger life
and property.
BTW What ever happened to fiber optics?

"Harmful interference" is a specific technical term of art in
communications regulatory law that refers to interruption to a
licensed communications service and places the responsibility to
alleviate the situation on the operation causing the problem.

Your neighbors will experince "unwanted interception" which you
have no obligation to deal with except to make a reasonable amount
of tests to enable the neighbor's repair tech to check the
effectiveness of whatever protective measures they are making to the
affected home electronic/entertainment equipment.

You, OTOH, will receive "harmful interference" from the BPL operation.

Go get 'em, tiger....

If you have an analyser, connect the outlet to 2 series 25 ohm
resistors. (27 will do). The swr should be 1:1 or near.

Then run a fly wire with clips from input shield to the center
of the 50 ohm load. ('Round the balun).
If the output is truly balanced the swr
will remain 1:1 but if it is'nt the swr will jump to 2:1

This is a test for isolation of the feed shield from the load
- good for any balun.

If you have the gear, try it.

Cheers.

The forward power is 103 watts and the reflected power is 3 watts in
the given example. The signal generator equipped with a circulator
load is putting out 103 watts.

you have lowered the impedance of the antenna, not the resonance, and thus have a mismatch at the junction of the antenna and the feedline, which causes the swr. You can add a balun, change the impedance of the feedline, or transform it at the transmitter either with an additional piece of coax, or with a tuner.

What is the maximum Z0 possible with transmission line? Seems that would
be the feedpoint impedance of a traveling wave dipole.

But that sourcing and sinking is occurring *INSIDE* the SGCL(150). The net
power inside SGCL(150) is 100W dissipated, *exactly* like the other scenario.

The shortcoming I notice is your sidestepping of the question: What happened to Pref1=25W? It just seems to have disappeared when we turned on SGCL(150) and the 33.33W wavefront arrived at the impedance discontinuity. What could have possibly made Pref1 disappear?

It's not clear why you'd make that assumption.

A transmission line doesn't radiate; a traveling wave antenna does. The feedpoint impedance of a traveling wave antenna is dictated by both the termination resistance and by radiation. The characteristic impedance of a transmission line isn't a function of either.

You can make a transmission line with an arbitrarily high impedance, although because of the nearly logarithmic relationship between wire diameter/spacing and Z0, values of more than a few hundred ohms (for open wire line, and considerably less for coax) become impractical. Of course, you'd have to go to very low frequencies to make use of very high Z0 transmission line, to avoid line radiation or, in the case of coax, propagation of other than TEM waves.

And, just out of curiosity, how would you construct a traveling wave dipole?

What you have done is to put a resonant parallel tuned circuit on the output end of the 50 Ohm resistor. After 1/2 cycle of RF, the voltage on the two ends of the resistor is equal. Hence no power is delivered from the source, provided it is lossless coax.

Tell me if I am wrong, but you could put an HP oscillator and a transformer that delivers 70.7V into an open circuit in place of the 100W amp, and in the steady state you would reach the same conditions. It would just take longer. If the Bird read 100W before, it would still read 100W. Assume it is a perfect WM that does not absorb any power. If you buy the tuned circuit analogy, the WM is in effect measuring circulating current in the tuned circuit.

Here is what I think the problem with trying to understand reflected power in transmitters is. On the one hand, you have forward and reflected power in and out of a black box. On the other hand, open up the black box and measure the IMPEDANCE back towards the load. Without knowledge of reflections, we know from the Smith chart how a misterminated line is going to change the load on the collector of the transistor, and hence cause it to change its power output. So, in the impedance analysis there is no concept of absorbing reflected power.

You don't like talking about pulses, but that is the way I was taught reflections. We used "Electromagnetic Energy Transmission and Radiation" by Adler, Chu, and Fano. 1960 (gulp!)

The energy flowing in a flat transmission line goes somewhere.
The energy flowing in a traveling wave antenna goes somewhere.
Both systems are flat so they seem similar to me. A terminated
Rhombic radiates and has approximately the same feedpoint impedance
as wide spaced transmission line.

> And, just out of curiosity, how would you construct a traveling wave
> dipole?

In my head or in real life? A terminated Sloping-V comes to mind.

> not absorbing the reverse power.

If "the source is not absorbing the reverse power", then the reverse power is being re-reflected to become the forward power. During steady-state, the forward power is not coming from the source so it has to be coming from a re-reflection process. It can only come from one of those two places. In a lossless line, you could disconnect the line at the source and there would still exist forward energy and reflected energy. The reflected energy would be reflected from one open end and the forward energy would be reflected from the other open end. It's essentially a super-conducting ring that has been cut and straightened out.

Make the stub one second long and you will have 200 joules stored in the line. The source will have supplied all of that 200 joules with the voltage and current in phase, i.e. it was supplied as joules/sec.

thanks for the advice.
It is much appreciated.
The only question I have now is probably a daft one but here goes..... the
plans for this antenna specify that the reflector should be at position 0 on
the boom and D13 should be at 8300mm relative to the position of the
reflector.. Where would one drill the hole for the reflector ? i.e how far
in from the end of the tube, and how far past the hole for the last director
would the boom actually end ?

You can make up just as much power bouncing around inside the cable as you'd like. Add it, subtract it, vectorize it, Barry Sadler & Lou Adler it, store it, superimpose it, put it on the Group W bench, whatever you want. Argue about it for months, as you have been.

But you can't say the reflected power is coming out and heating up the source. It isn't.

I don't completely follow the HP oscillator bit, but you can change the
source resistor to any value, and get exactly the same steady state
result. As you say, the resistor value only affects how long it takes to
reach steady state.

If the Bird read 100W before, it would still read 100W. Assume it is

There are lots of problems with analyzing waves of average power bouncing around in a transmission line. I'm sure that every one of them has been pointed out many, many times in postings directed at Cecil.

The fact is, that whatever is going on inside the line, the "reflected power" isn't flowing out and heating up the load. My example shows that. (Again, you can find other examples in the text file on my web site if you're interested.)

>
> You don't like talking about pulses, but that is the way I was taught

You betcha I like to talk about pulses. I spent several years at Tektronix as a Principal Engineer designing high-speed sampling scopes and TDR systems. I've written and taught courses on TDR, and on many occasions helped our customer support folks deal with questions they weren't able to answer.

But there are some important differences between steady state sinusoidal conditions and single pulse conditions. I mentioned one -- that in the pulse case, the source is off but not in the steady state case. That makes a big difference to what happens when that reflected pulse arrives back at the source. Don't mix the two conditions, or you'll be led badly astray.

If the hole is far enough from the end that it doesn't weaken the element mounting mechanically, that also seems to be OK as regards the electrical effect of the metal boom.

It's nice to use plastic end caps (most yagi manufacturers will sell you a few) so the practical distance for the holes is just far enough so that the end cap will push in without fouling anything inside.

Or make it about pi/2 times the width of your thumb, and then trim the end cap until it fits... no worries.

Many years ago, in a previous lifetime of exactly this same discussion, a former engineer with an RF semiconductor manufacturer explained exactly how these figures get into the data-sheet.

Here's my recollection, which is backed up by information from 'RF Transistors' by Dye and Granberg (Motorola).

You can design a new transistor for certain performance parameters, but this isn't a cookbook thing. In the end, the applications engineer has to fire up the new device in a test jig to see what it's got.

Variable impedance-transforming networks interface the input and output of the transistor to 50R. The driver source is a high-level signal generator with a defined 50R output impedance, and there's a 50R load equipped with the usual wattmeter and spectrum analyser. There is also IR sensing of the temperatures on the chip.

The engineer then plays with the input power, input network and output network to get the best results - "best" in terms of gain, output power, efficiency and linearity (if relevant), all without coming too close to the limits of voltage, current and chip temperature which have already been derived from breakdown testing. Actually the device needs to operate some way below these absolute failure limits, because long-term reliability is also an important factor.

The applications engineer is probably going to kill lots of devices when pushing the limits, but eventually he'll find out what performance the device can safely and reliably deliver.

Note that gain, output power, efficiency and linearity are in some ways contradictory. The judgement about "best" performance comes partly from the design aims for the new device, but just as much from the engineer's own skill and judgement in adjusting the test rig to give the best possible balance between these opposing factors.

Having found the optimum settings, the measured gain, input power and output power are copied directly into the data-sheet.

The transistor is then removed and a network analyser is connected where the base/gate of the device was. With the driver source switched off but

still presenting a 50R load, the impedance at that point is measured. The conjugate of that measured impedance is the device input impedance that you see in the data-sheet.

The network analyser is then moved to where the collector/drain had been. The measured impedance is the optimum load impedance that needs to be presented TO the device.

Here's where it gets a bit messy. Some data sheets present this measured value quite clearly as "load impedance", but others present the conjugate using the misleading term "output impedance". It's easy to tell which is which, because the device is invariably capacitive, right at the collector/drain itself; so you can be sure that something involving "+jX" is the measured load impedance from the outside world, while something involving "-jX" is its conjugate (unless there's a significant internal impedance transformation inside the package).

The really misleading thing is that the output network you need is the one that would match the conjugate of the load impedance to 50R. It's then very easy to jump to the conclusion that you've "matched the output impedance of the device" - but you haven't. All you've done is to present the device with the optimum load impedance that the manufacturer has found out purely by experiment.

All this was written in terms of transistors, but much the same is done when characterizing new tubes, especially as regards the optimum output load.

Finally, note three things:

* The function of the output network is to present the optimum load impedance TO the device FROM the outside world.

* What's "optimum" is not dictated entirely by the device - it involves a lot of judgement on the part of the applications engineer. It's all done on that there bench :-)

* The output impedance of the transistor doesn't come into the story at all - not when characterizing RF power devices that are not operating in class A. Even the device manufacturer doesn't know or care what it is. Neither need we.

Please explain why the table is nonsense, if you claim it is!

Please be a bit creative yourself.

And Netscape: we stopped using that about 8 years ago...

Rene

"Frank" wrote > I can install only an inverted vee:
> each side max can measure about 17 feet
>
==========

Make horizontal distance between ends of wire = 34 feet.

Make mast height = 31 feet.

Make ends of wire 3 feet above ground.

The apex angle will be 62 degrees.

Resonant frequency = 7.2 MHz.

Dipole feedpoint resistance = 30 ohms.

SWR on 50-ohm feedline = 1.7

Feedline length = 58 feet.

Efficiency = 37 percent.

Loss relative to a 1/2-wave dipole at a height of 100 feet = 0.7 S-units.

And there you have your 40m inverted-vee dipole.

Which can be modelled using program INV_VEE from website below.

Download INV_VEE in a few seconds and run immediately.

First, you woundn't need a "trap" to cover 40M. The antenna is already too short to resonate on 40M. What you need is a loading coil in each leg. If you have an antenna tuner, you will be able to use the antenna on 40M if the tuner is able to match the antenna's impedance to that of the radio. Maybe you can put up a horizontal loop for 40M...each side would measure about 35 feet, which I assume is all the room you have in any direction.

Best of luck,

Scott

just one example:

you see with first glance that the claimed gain figures are
much to high,
how can an antenna 30% longer than a halfwave show 3dbs of gain
and 1/4 Lambda more yields in another 1,5db more gain?

>

All for naught in enough cases to render QRO a complete waste Cecil.
The BPL crud is hammering yer rcvr with an S9 signal. It's the bottom
of the cycle. The VK with his two gallons is 10,000 miles away and
maybe an S6 on a good day. No contact.

160m is below the BPL target spectrum so far. Break out those 160m
condo hamburger deck railing-mounted aerials and beat yer brains out
that way. Choices, choices . . .

I have been a Netscape user for almost 8 years. I refuse to use IE!!

I spent years writing HTML based web pages in HTML!! And, I always Beta tested my pages against all available browsers.

The current software for designing web sites is compliant with the Bill Gates world, but, the world is bigger than Bill Gates.

Dave, the context of "I refuse", is nothing more than an attitude adjustment problem.
;-)

> I spent years writing HTML based web pages in HTML!! And, I always Beta
> tested my pages against all available browsers.

I've written HTML-based web pages also. And of course I always Beta test my pages as well. However "all available browsers" includes only two: NS and IE. My final tests always come out correct when testing with IE. Usually there is some little quirk with NS. That is the reason for the statement at the bottom of the page, "This site best viewed with Internet Explorer", and includes a graphic link to MS if you want to download the IE browser.

You can view the web pages with NS if you want, but the "disclaimer" is there for a reason. The guidelines that govern what nomenclature is used to make up HTML code has some differences between NS and IE. Until both companies agree on the same actual code, there will always be problems - unless you know *both* variants of HTML programming.

Tubes and transistor power amplifiers quite oftem
use negative feedback to improve SSB linearity.
Improvements of 5 to 10 dB are common. The
negative feedback reduces the internal impedance
of the tube and transistor amplifiers. The
tube/transistor data sheets do not consider this
factor.

Again, we usually don't really know or care much
about the values of the internal impedances.

But there is a special case. Voice/music/data tube
transmitters operating at low frequencies have a
problem called "sideband clipping" where the plate
tank selectivity may be too sharp and reduces the
modulation bandwidth. The internal impedance tends
to broaden the response at resonance. When
designing the tank circuit this effect may have to
be included.

wrote:

>
>Maximum power is when you turn your metal 6L6 upside down in a glass of
>water during a contest. :-)

What I have learned so far:

If you have a 100 watt transmitter, the watt meter shows 3 watts
reflected. I deliver 103 watts to the antenna. I now know where the
reflected power go's. But where did it come from? If I could find a
way to have 100 watts reflected I could put 200 watts to the antenna
from a 100 watt transmitter.

If my transmitter has an output impedance of 50 ohms, all the
reflected power will be absorbed by my PA. I need to find a way to
change my output impedance to something other than 50 ohms?

If I could make my SB-401 act like a radar transmitter, and time the
pulses correctly, I could cancel out the reflected power pulses.

For some reason I need a circulator on my SB-401.

To get max power out my 6146's I need to turn them upside down in a
glass of water? :-)

Hello Peter,

I saw again your negative comments.

Renember my diamond info is based on dBi,
2,15 less and you get dbd.

Do you think diamond want to risk there name to
put some false gain numbers on the antenna?

If a antenne does not do what it is expect to do
we can claim the money back.
Do you realy think diamond would take that risk?

Why do you think diamond has verry expensive
measure equipment?

Im wondering were your homepage is, I asume
everything must be perfect on your homepage.
So maybe you done a lot of work too (like i did),
so there might be some intresting info? (let us know!).
I saw it wasn't ready on qsl.net server.

Hello All,

Sorry for the netscape users.
I used netscape browser many years back, Im glad
with the microsoft browser.
Netscape gave me some problems with some
goverment page's (wich microsoft ie doesn't).
Netscape does not know all the html code's like
the fixed function in the background sentence (and
many more).

These fixed command is verry famous in the
internet world.

But do not worrie netscape comes with updates
they are always a littlebit later than microsoft!

I have no homepage and do not need one for my ego,
but I told you already, if somebody advertises his in newsgroups
as spam, he should make shure it is readable not only with IE.
Usually it is enough to make shure, search engines as Google
collect that stuff.

> source. It isn't.

I didn't say it is, Roy. I said one of two things has to happen - either
the reflected energy flows into the source or it doesn't. If it doesn't,
it is obviously re-reflected. If the source is not furnishing the forward
energy, then the re-reflected energy must furnish the forward energy. There
is no logical problem. The Bird wattmeter is reading the forward and reflected
joules flowing past a point in one second. That energy is really there. If
you make the stub one second long, the stub contains 200 joules of energy
that cannot stand still. The standing waves prove that the forward-traveling
energy wave is 100 watts and the reflected-traveling energy wave is 100 watts.

And none of them are a problem to explain. If there's energy in a
system and it's not presently coming from the source, then it
exists as forward and reflected wave energy that previously came
from the source (in a single source system). All you need to do
to figure everything out is keep track of all the energy.

The key word is "to", not "accepted by". You can indeed get 200 watts
to (incident upon) the antenna with a 100 watt transmitter. Trouble
is, the antenna only accepts half of that power.

Thanks for that information. A related topic would be the effect of
tank circuit Q on the bandwidth of HF amplifiers; I seem to remember
reading something about, but don't recall what it implied about the
magnitude of the tube internal impedance, as compared with the load
impedance.

There is a mechanical engineering standard on that. The issue came up re the A310 design after the NY crash where the tail tore off . I believe the standard is 2 hole diameters. I looked at my VHF beams, and they are about 25mm.

Ian,

Thanks for the lowdown. I am saving the message. I looked through the Moto RF book last night and noticed some specs spell out by what they mean by output impedance (conjugate of load), while others don't. Newer ones seem to qualify it. Since the efficiency of these devices is usually around 50%, you can't tell which is which by looking at the numbers.

I have designed several 6m amplifiers by choosing the parallel load resistance based solely on VCC and desired PO, and it always worked.

Roy,

I think I have the complete solution to your 70.7V generator and 1/2 wave line, but with a finite load. Part of it implies that you are correct. Part of it seem weird, even though the numbers add up. I analyzed it both as a circuit element and as a transmission line problem. Kind of long, but I'll post it if you want to see it.

> Exactly like the other scenario, yeah, like the extra .033 Kw makes no
> difference. That's a good one, Cecil :-)

In the first scenario, the 0.033 Kw was loaded into the system before
steady-state conditions were established. The s-parameter equations
consider the power reflected from a mismatched load as another source
of power in the system. The two scenarios are very similar.

But forget the first scenario. What happens to Pref1 in this scenario?
It takes a 25 joules/sec wave to cancel a 25 joules/sec wave.

Vfwd1(rho) = 35.36V at zero degrees, Ifwd1(rho) = 0.707A at 180 degrees.

Vref2(tau) = 35.36V at 180 degrees, Iref2(tau) = 0.707A at zero degrees.

Each of these rearward-traveling waves contains |35.36V*0.707A| = 25 joules/sec

They superpose to zero. What happens to that 50 joules/sec of rearward-
traveling energy? We already know it winds up in a forward-traveling wave
toward the load. You have already admitted that wave cancellation is
responsible for Pref1 being zero. Waves simply cannot exist without energy.
When waves cease to exist, they are forced to give up their intrinsic energy.
We know that Vref2(tau) is traveling rearward. That's all we need to know.
Vref2(tau) is the same voltage term as s12*a2 in the s-parameter equation.

When b1=0=s11*a1+s12*a2, what happens to |s11*a1|^2 and |s12*a2|^2? We
know that s11*a1 and s12*a2 are rearward-traveling voltages.

Unfortunately, he didn't say what happens to the intrinsic energy
necessary for those two canceled waves to have existed in the first
place. The question is: At the moment that two waves are canceled,
do they give up their intrinsic energy components? Or, as in the sour
grapes tale, were they never associated with any intrinsic energy to
begin with?

I can not get the reson. freq. in the band..for example..everything is low in frequency:

10 Meters center freq. 27.262 MHz.
15 Meters " " 20.895 MHz.
20 Meters " " 14.653 MHz.

The Vertical is ground mounted with radials.....,manufact. spacing cannot be adjusted any further...I used a mfj ant. analyzes. to measure the reson. freq,..anyone else had this problem..if so, how did you fix it...any suggestions would be most appreciated...tnx.....Gary..K8BY

1625. Re: Question for Roy Lewallen

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-19 19:08:12 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vhj5p0rinme17f@corp.supernews.com>
Source record: 112268

No need, I've done both transient and steady state sinusoidal solutions
for the general case many times. The source impedance dissipation and
power supplied by the source can be entirely determined simply by
replacing the transmission line and terminating impedance with an
impedance equal to that seen looking into the input end of the line. It
becomes a simple, three-component electrical circuit. You can replace
the transmission line and load with any combination of length, Z0, and
load impedance you'd like, as long as the input impedance is the same,
creating just about any amount of "reflected power" you want, without
changing the source dissipation.

The "reflected power" is not dissipated in the source, matched or not.
It's trivial to show that this is true. But people still want to believe.

>

Clearly, neither of us are PhDs in EM wave propagation, but water
certainly has a different E versus H impedance than the 377 Ohms of
free-space, which is why the input impedance of the antenna will
change. This is not the same, but similar to how the load on the
secondary will affect the primary impedance of a transformer.

> > Do you think that the characteristics of a transformer of a

> that an antenna is fundamentally an impedance matching device.
>

Well, you've already agreed that an antenna/transducer can be
considered one half of a transformer, but what i'm saying is that the
permeability of the core or medium will certainly affect the impedance
of the transducer.

What do you mean by "adequate core"? One that suits your purpose
i suppose. But a material of the wrong permeability will definitely
affect your transformer performance. So the impedance of the core
definitely affects the transformer characteristics, as does the
impedance of the air (or water) between two antennas.

> I see that you won't be swayed from your visualization. But hopefully
> some of the other readers can see the fallacy of the concept. I think
> I've done all I can, so I'll leave this topic now.
>

You've convinced me that antennas are transducers, which are one
half of a transformer, by giving me logical statements.

But you have not come up with anything to convince me otherwise
on this point, which i don't believe is a fallacy at this time.

I'm not a small boy Roy, and I'm an engineer too. Your NG
inspired sarcasm doesn't change my opinion at all, and cannot even be
compared to logical reasoning.

Roy, thanks for your insight, and you have definitely helped me
out with your strict semantics (sometimes needed, especially in the
engineering world!).

But your need to be always right closes your mind to new ideas
and new learning. This is the sign of someone who claims to know
everything about a subject, which i personally believe to be
impossible, even for such a specialized topic as antennas (actually,
it's quite broad, isn't it?), and even for someone as bright and
knowledgable as you are.

Again, much thanks for your input.

Dr. Slick

If reflected energy could not cause over-current/over-voltage
problems in the source there would be no need for protection
circuitry. I once burned up a pair of ARC-5 1625's because my
feedline came unsoldered at the antenna. If there had not been
any reflected power, it would not have happened.

It is reflected back toward the source. It causes standing waves
and additional losses in the transmission line.

>>>For some reason I need a circulator on my SB-401.
>>
>>Only if you allow reflected energy to reach your SB-401.
>
> How can I stop it from reaching my SB-401?

Does the SB-401 have an adjustable Pi-net output? If so,
you can adjust it for a Zg-match which will keep reflected
energy from being incident upon the SB-401 amp. If not, you
can use an external antenna tuner.

Gary -

According to the data you provided:

10 and 15 meters -- length is "too long"

20 meters - length is "too short"

[Remember that physical length and electrical length are different values
with this antenna -- because of the usage of traps]
http://www.new-tronics.com/main/html/base_hf_6_band.html

I would suggest reading K5RWK's column in "The Chawed Rag" newsletter
on installing the Hustler 6BTV vertical

Here is that web link:

In part, of course it is.

The standing bias controls one fixed point on the line.

The load, transformed backward through the output matching network,
controls the slope of the line.

Finally, the drive power controls how far the instantaneous operating
point moves along the line.

Which is a V/I ratio - which is an impedance. Could this be the impedance
"seen" by the reflected waves transformed through the output matching network?

Most due to crappy power lines and insulators. Now add BPL with wideband
digital signals and you have a notion of how it will sound.

I have been working with Alabama power for almost 5 years now. Including
the ARRL and the FCC on their ass. And its still not fixed. Wait till
BPL is deployed.

1636. AM Broadcast band antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-19 23:14:42 UTC
From: Dave Pitzer <dpitzer@sonic.net>
Message-ID: <ChkSa.3291$dk4.155901@typhoon.sonic.net>
Source record: 112180

I'm going up on my roof later this week to repair and paint my chimney. I'd like to take the opportunity to at least start an a.m. broadcast band antenna (long wire??) using my chimney as the anchor for one end.

What kind of wire shoulds I buy?. Alumimum, copper? What gauge? What can I use for insulators. What's a good way to ground it?

I have lots of trees in both the front and back yards for the "other" end. Given this flexibility, about how long should the wire be. Would the wire ideally be parallel with the (flat) terrain of the yard?

Directionality: Assuming most of the a.m. station I want to DX are in the general direction of southeast of my house, should I run the wire SE - NW or NE-SW.

Downlead to receiver??? (receiver has external antenna input -- ground and "hot".)

Is there a Web-site I could/should investigate or a more appropriate news-group?

Many thanks,

Dave Pitzer

The older MFJ don't work well with trap antennas check your documentation on
that one.

Im trying to remember. I think the Hustler says to adjust from the highest
band first. Its been a long time since I had one.

Cecil,

You seem amused. Actually, this is the procedure given in several Motorola application notes, including AN282A. It is the real part of the parallel equivalent load. Interestingly, I recently ran across a design procedure for an 813 tube amplifier where they went through a long convoluted process to come up with a load resistance. Using the Moto formula, I got precisely their number in one step.

Yes, I know the obvious is sometimes amusing. What is amusing to me is
the endless arguments over the internal impedance of an RF amplifier
when the load is in control of the amp's load line.

A one quarter wave length wire, pretty much the minimum size for a tuned antenna, is 235 feet long in the middle of the am broadcast band. Ideally this wire would be at least 1/2 wave, or 470 feet, in the air. In order to become directional a log-wire needs to be multiple wave lengths long, I would guess directivity we become noticeable at 5 wave lengths. That translates to 20 times the above dimension, or 4,700 feet.

That said put as much wire as you can, as high in the air as you can get it. It will be an improvement over what you have now. You might also consider building a "shielded loop", especially if you want directivity. This is an indoor antenna, generally made from coaxial cable, and because of it's properties your apparent reception will be greatly improved.

The stuff I did point to the actual impedance, not the SWR that does the bad thing. For instance, a load of 25 Ohms greatly increases the internal dissipation; a load of 100 Ohms greatly reduces it. If you go too high with the impedance, you start to saturate the hell out of the device, and other things happen.

Did you melt the plates on the 1625s or burn out the grids? Your feedline might have opened an odd multiple of 1/4 wave from the radio.

That is all true, but missed the *most* important thing: DON'T
use the chimney as one support for a wire antenna.

In particular not if the other end is tied to a tree!

The reason is because chimneys are not designed to handle any
significant horizontal loading, and putting almost any real
length of wire up is going to stress the chimney and damage it.
Worse yet would be anchoring the opposite end to a tree that
will sway in the wind, and more than likely damage the chimney
during the first wind of any significance!

Note also that as mentioned above, the height above ground is so
low, and the length so short, compared to the wavelength of the
signals of interest, it doesn't really make a lot of difference
just how high that one end is. If it is tied to the house at an
appropriate point, or use some other support, the fact that it
could be 5 or 10 feet higher just is not important.

Dave -

There are many web sites on the Internet for Short Wave Listening (SWL) and
also at least a couple magazines - such as Bob Grove's Monitoring Times.
http://www.monitoringtimes.com

Universal Radio is a very good store that specializes in products for the
SWL as well
as the amateur radio hobbyist.
http://www.k7on.com/scan-swl/swl/

First, SAFETY is paramount in your antenna installation.
http://www.universal-radio.com/catalog/sw_ant/safeswl.html

For antenna building I always suggest to beginners that they learn by
looking at
commercial products (especially the ones that work well)
http://www.universal-radio.com/catalog/sw_ant/2205.html

http://www.alphadeltacom.com/pg7.htm

http://www.odxa.on.ca/beginnersguide/swhear.html

For AM broadcast (SWL) antennas, I have used everything from 20 gauge speaker wire
to 14 gauge electrical wire (with choice of insulation color) used in electrical conduit [not Romex]
http://www3.damien.edu/students/mskim/shortwave.html#Anchor5

A good ground rod is very useful for a proper installation.

The haggling, for years, about congugate matching, SWR, forward & reflected power, silly virtuallty, etc, has gone on long enough.

Only G3SEK, amongst the small minority of the radio population who contribute to these walls, has a grasp of what it's all about. There are obviously others who are too busy to waste their time on newsgroups.

But who am I to judge?

INTERNAL IMPEDANCE OF RF POWER AMPLIFIERS

Programs TRIODE1 and TETRODE1 assist with the classical design of tube (valve) power amplifiers. They are very closely related to each other. A key design feature, the cathode current operating angle, is an input parameter.

Apart from the drive and input-circuits, they also apply to their lower power transistor equivalents.

For the benefit of those who may insist on knowing, these two programs are based on the clssical theoretical analysis by americans Everitt, 1932 (who was probably not original at that relatively late stage of the thermionic tube). He was followed by Terman in a more practical but more uncertain manner in the 1940's. No doubt there have been others. None of them, aware of their weaknesses, would have wished to be worshipped as little tin Gods.

The basics havn't changed since Ohm, Ampere, Voltaire and Heaviside.

Anyone responding to an enquirer, who feels in need of extra support in his reply, who refers back to the ancients merely displays his inability to provide a logical explanation and a lack of underlying understanding. There's nothing wrong, of course, in a lack of understanding except in propagating it. (Most enquirers do not have the ancient books or easy access to the books anyway)

Neither of this pair of programs require a congugate match between internal impedance and the load. There's nothing magical about 50 ohms. It could be any value as any appropriately designed SWR meter will assume. I have a 75-ohm model. All is based on assumptions. The only absolute value is SWR itself which does not depend on Zo or Z load but merely on their ratio.

The only way to determine dynamic internal impedance of a PA is to calculate it AFTER THE AMPLIFIER HAS BEEN COMPLETELY DESIGNED. It is then too late to have any effect on design.

Just to satisfy curiosity the dynamic internal resistance of an amplifier is a calculated output quantity of program TETRODE1. It is of course of no practical value. In the program it is referred to as the Source Resistance when looking back into the 50-ohm output socket.

Dave,
The wire should be large enough to support it's own weight
plus a little bit more. The 'best' kind of wire to use is
whatever you have the most of. Mixing sizes of wire certainly
won't hurt anything either.
The antenna should be as long as you can conveniently afford,
both in price and in 'realestate'. Longer is better. Unless
you have a lot of realestate, your antenna isn't going to be
very
directional so pick the 'easiest' direction to put it up
consistant
with keeping the 'significant other' happy (and the neighbors).
Since you are going up on the roof to fix your chimney, I
think
I'd find another place to hang one end of your antenna.
Chimneys
are not as strong as people think (especially one that's been
fixed).
Depending on how 'whippy' the other end is (tree?), you may be
re-fixing your chimney soon.
'Doc

Dave:
I quickly scanned the responses to this point, and no one gave you the correct guidance. In this present day environment, if you are interested in BCB DXing, forget electric field (wire) antennas. Too much noise. Unless you live in the middle of the desert, and are willing to forgo modern conveniences, all an outside wire at BCB will give you is more noise. Start looking into shielded loops. Lots of information on the 'net about them. Up to about 3 MHz, they will outperform wire antennas hands down anywhere except "clean" government receive sites. And, even there, shielded loops are the antenna of choice for BCB intercept, and lower frequencies. See, for example "Hermes Loops" on TCI's web page. I forget who else makes them, but the government buys lots of them.

Now, if you are interested in Short Wave reception, that's another matter. But pitfalls lurk there also.

>any reflected power, it would not have happened.

Transmitters are damaged *only* by excessive heat dissipation, voltage or current, all caused by the wrong value of load impedance. Reflections don't come into it.

Think what would have happened if you had measured the impedance at the TX end of your o/c transmission line (very high or very low, depending on the length) and replaced it with a resistor and inductor/capacitor giving the same value of R +/- jX.

There's no transmission line, so no traveling waves of anything, and no reflections - just a transmitter with a very wrong value of load impedance. The 1625s would have burned up just the same.

And please don't tell me there would be reflections inside the tank circuit... if you do, I'll take the tank circuit away too, and connect a wrong load impedance (the output load, now transformed through the tank) directly to the anodes!

Hi All,

As offered in other postings, I challenged for some to differentiate
between themselves as Equipment Operators, Bench Techs, and
Cut-And-Paste Theoreticians. The "oomph" we all got from that
response was, as I also offered, the uncomfortable groan of avoiding
serious testing to instead indulge in eternal debates, the offering of
puzzles, and the recitation of dead white men's work.

So it follows that I am as responsible as others to differentiate
myself to the standards I set - it takes some time, but is not
seriously difficult. The quality of that differentiation is clearly
in the opprobrium above which maintains "it doesn't really matter" and
I can accept that, again, by my own terms of
"Does it make more than 1dB difference?"
which is more a quantitative test than the philosophical, qualitative
assertion that got us here.

The difference lies in a particular Engineering Note offered in the
1960's by Hewlett Packard: "Microwave Mismatch Analysis, Application
Note 56."

This note in turn references the work adopted by the National Bureau
of Standards published in IEEE Transactions of Microwave Theory and
Techniques, Vol. MTT-11, no. 3, May 1963, p. 179, by R.W. Beatty.

These references were then expanded in book form "Microwave Theory and
Applications," Stephen F. Adam, Prentice-Hall, 1969.

I took my training in the only school of Metrology in the US in 1972
and took these works to heart, by far and away not because they were
so much academic (even though they qualify in spades beyond all lesser
discussion), but because they were written for real engineers employed
in real measure employing real tools.

So much for Hubris, my own or others.

The simple fact of the matter is that if accuracy is not your cup of tea, you wouldn't have read this far anyway. If you are concerned with accuracy, and by that I mean making valid measurements of RF power, then the Z of your source is exceedingly important in the face of a mismatched load.

To wit I offer a simple verification of this observation and the works enumerated above.

1. Take one Ham transmitter capable of supporting 5 to 10W into any load without its ALC engaging and altering the power (this simplifies matters but is not strictly necessary).

2. Obtain four 50 Ohm loads each capable of supporting that same 5 to 10W power without causing any of those loads to change Z (this is NOT as simple as it may seem, but is not that difficult if you don't take it for granted). Power will never be applied for more than 10 seconds in any case during readings (or as long as it takes for your transmitter to settle to a stable power).

3. Obtain a Wattmeter capable of reading both forward and reverse power, where 5W is full scale deflection for the forward and reverse power.

4. You will need an assortment of cables and T connectors (choose your own connector style suitable for the frequency that you can support these methods to be described, following).

5. Confirm ALL loads do not exhibit a reverse power reading for full power (that same 5 to 10W) applied to them, one at a time, through each and every cable.

5a. For the purposes of my demonstration, I employed a device of my own design that I call my BVT, a Binary Variable Transmission line. It contains an assortment of coaxial lines arranged such that they can be inserted, inline, in 1 foot increments, for 0 through 32 feet. If this sounds familiar, it was the subject of my very first posting to this group some 8 years ago.

6. Apply one of those 50 Ohm loads in parallel, directly across the transmitter output. Use a T connector to allow another line to be connected in parallel as well. This port will be called the "Plane of the Source."

7. Combine the remaining (3) 50 Ohm loads in parallel using two T connectors such that one port remains open to accept a line to be connected in parallel as well. This port will be called the "Plane of the Load."

8. Connect a length of transmission line from the Plane of the Source to the input of the Power Meter; and in turn, connect another line from the output of the Power Meter to the Plane of the Load. The center of the Power Meter (actually one port or the other depending on

which line you will vary in the future) is the "Plane of the Measurement."

8a. I have chosen to use a 2 foot line to the input of the Power Meter; and at the output of the power meter I have a 3 foot line connecting to the BVT (which contains 1 foot of line in the zero position) with another 3 foot line at the BVT output to the Plane of the Load. As such, I had the capacity to change the position of the Plane of the Measurement by 32 feet by one foot additions from a minimum separation of roughly 8 feet. This also elongates the distance between the Planes of the Source and Load from 8 feet to a maximum of 40 feet.

9. I selected 24.9MHz by accident of meeting the Power Meter's sensitivity and the transmitter's capacity to load this enormous mismatch - it also happened to be eminently suitable for the data that follows.

ALL data was taken by first setting the output power to force a forward power reading of 5W (full scale) for EVERY variation, and then taking the reverse power reading:

Initial reading 1.70W reverse
added 1 foot 1.45W
2 1.20W
3 0.95W
4 0.80W
5 0.60W
6 0.50W
7 0.45W
8 0.75W
9 0.80W
10 0.90W
11 1.00W
12 1.20W
13 1.30W
14 1.40W
15 1.45W

So, by now it may become apparent that:
there is only one mismatched system condition;
that condition is not impacted by any ALC action (either through it not being engaged, or being nullified by maintaining a constant forward power);
no change in the line conditions inject any additional mismatch (the BVT is flat through all settings 0-15);
there is a substantial difference in what the apparent Power is.
there is a substantial difference in what the apparent SWR is.

The power determination for this system mismatched condition, i.e. a power meter between two Planes of discontinuity, exhibits a low of 3.30W to a high of 4.55W depending on its position in, and the length

of the path between the Planes of discontinuity.

Hence the answer to the question of what difference does it make?
-1.395dB
Which also answers my standard: does it make more than 1dB difference?
Yes

It then follows that for a source that exhibits a 1:2 mismatch that is feeding a 1:3 mismatch through a 50 Ohm system, you can always expect some error, and that if you are ignorant of the dimensions, that error can be as great as roughly 1.4dB.

What do the experts calculate? Well, I won't go into that math, that is left to the student to find through research from any of the three references cited. The graphs offered by each of them only allow for a 2:1 mismatched source facing a 2:1 mismatched load which in turn will yield up to a 1dB error.

Why the deliberated mismatch at the source? It refutes the myopic discussion of source Z by rendering a known value in parallel with an unknown (sic) which, when is 50 Ohms in itself, must render a source that is NOT 50 Ohms (guaranteed in fact, and supported by the evidence of data forecast by methods adopted by NBS).

>we can claim the money back.

I never would buy a diamond antenna if there are better alternatives
available, and in most cases there are!

>Do you realy think diamond would take that risk?

Yes, because many radi amateurs do not realize that the antenna does
not what it should...

>Why do you think diamond has verry expensive
>measure equipment?

At least they must get their antennae to work. But I also wonder what
they have this for?! Even several antennae from same type and same
production lot differ significantly!!

operation.

but is that a real resistive 50 ohms, or a dissipationless 50 ohms non-resistive? or could it be a virtual 50 ohms hiding some other fake steady state value? you can't read it when you connect an ohm meter to the output connector, so how can it be a resistance? or is it really a complex impedance that can be ignored when you calculate the output power? but then again it might be due to internal reflections making it an infinite sum of many other factors? maybe we have to learn how to conjugate our impedances before we can have a decent discussion about it? but what if its only a matching system to free space impedance? when there are reflections does it reflect or absorb? who started this topic anyway????

1656. 2 x DELTA LOOP stacked for 144 MHz -> how to connect them ?

Newsgroup: rec.radio.amateur.antenna

Hi to all,

This is my first request on this newsgroup
and I hope find help here.

Then, i want to stack 2 x 5 elements delta loop for 144MHz.
(horizontal stack)

The two antennas are built. I will adjust the first antenna
for the best SWR report and I will do the same modifications
on the second to have 2 equal antennas.

There will be 1 lambda beetween them.

My question is : how to connect the 2 antennas ?
is it necessary to use balun or is it possible to use a special
size of coax (50 or 75 ohms) to adapt impedance ?

I hope that you could help me.

shemas or draw will be welcome to explain.

Best regards

Oli

baluns change between balanced and unbalanced loads or sources, they are what you would use between a coax (unbalanced) and a 1/2 wave dipole or full wave loop (balanced), or to change from coax to twin lead.

to split power and combine two antennas it takes a transformer or two or three depending on how you want to do it. assuming the antennas are tuned for 50 ohms and you want to end up with a 50 ohm feedline the easiest way is to use a 1/4(or 3/4 if 1/4 is too short for your spacing) wave 75 ohm piece of coax from each one to a common T connector that combines them for the main feed line. a 1/4 wavelength piece of coax acts as a transformer, with a 50 ohm load on one end it will make it look like about 100 ohms on the other end, parallel 2 100 ohm impedances and you are back to a 50 ohm load for the main feedline.

another way is to use a balun at the feed point of your antenna that gives you a 100 ohm output, then use 1/2 or 1 wavelength piece of coax back to the T connector. the 1/2 or 1 wavelength coax will repeat it's input impedance on the other end so you get back the 100 ohms on the far end and then parallel two of them to get the 50 ohm main feed. this one is a bit worse than the one above if you are using high power as the swr on the phasing line is higher than the 75 ohm 1/4 wave pieces above, but for most people

this is not important.

there are lots of other ways to do it also depending on the feed point impedance and final coax impedance you want.

> don't come into it.

Reflections are the *CAUSE* of the wrong value of load impedance. The load impedance on a transmitter when reflections are allowed to reach the transmitter is (Vfor+Vref)/(Ifor+Iref). Please note that half the terms in the impedance equation are reflected terms. Please note that without the reflected terms, the transmitter would probably be perfectly happy with the "right" value of impedance at (Vfor/Ifor).

> Think what would have happened if you had measured the impedance at the

> reflections - just a transmitter with a very wrong value of load
> impedance. The 1625s would have burned up just the same.

Yes they would, but in that case reflections are not the cause of the impedance. In the first case, reflections are the *CAUSE* of the impedance that burned up the transmitter. Without the reflections, the transmitter would see (Vfor/Ifor) as the "right" impedance. With the reflections, the transmitter sees (Vfor+Vref)/(Ifor+Iref) as the "wrong" impedance.

Class-A and combined Class-AB are both linear. The impedance "seen" by
the reflected waves transformed through the output matching network IS
linear. The output matching network acts like a pendulum or flywheel.

Dr Slick,
Way back in this thread you alluded to antennas as being
transformers. The more I think about that statement the more I see
it as being fact. Anything that involved coupling which all
antennas do can be drawn as a transformer !
Since the thread migrated all over the place did you feel that
the group agreed with that position?

Yes, 1625's are pretty dumb but hopefully, we are smarter than the 1625's.
Here's more from the IEEE dictionary.

"resistance - (A) That physical property of an element, DEVICE, ...
(B) The real part of impedance. Note: Definitions (A) and (B) are
not equivalent ..."

"resistor - A DEVICE the primary purpose of which is to introduce
resistance into an electric circuit."

"impedance - (B) The ratio of the ... voltage ... to the ...
current ... (C) A physical DEVICE or combination of DEVICES ...
Definition (C) is a second use of 'impedance' and is independent
of definitions (A) and (B)."

"impedor - A DEVICE, the purpose of which is to introduce impedance
into an electric circuit."

In your above example, you changed the circuit from a (B) impedance to
an impedor. Even if the 1625's can't tell the difference, W5DXP can. :-)
Note that I, not the IEEE, capitalized 'DEVICE' in the above definitions.

>

At the junction (node) that separates the
amplifier and the transmission line, it is
necessary, and quite correct, to separate the
"waves" associated with the transmission line, and
the "circuit" associated with the tubes and tank
circuit.

If the transmission line input impedance is
replaced with a lumped LCR circuit, then confusion
disappears and we have a conventional problem in
AC circuit analysis.

The only assumption needed is that any
transmission line inside the amplifier has
negligible length. This is usually reasonable at
30 MHz.

1667. The myth that BPL is a solution for rural broadband

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-20 15:43:52 UTC
From: robkemp90210@hotmail.com
Message-ID: <6114e4af.0307200743.77d5e419@posting.google.com>
Source record: 112211
Cross-posted to:
rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.policy,rec.radio.shortwave

The claim that BPL is good for rural deployment is yet another myth propagated by the BPL lobbyists. In essence it is bait and switch. The BPL strategy is to get the FCC to allow the high levels of interference / pollution as the FCC is focused on getting broadband to rural communities that don't have it.

In reality, if the BPL lobbyists succeed, they will immediately focus on the wealthy suburban markets that are profitable (and already have cable and DSL) and ignore the rural areas.

DSL can work out to about ~ 16,000 feet from the central office. BPL can only go 2,000 feet from the BPL equivalent of a DSLAM, then BPL needs an expensive repeater installed by a linesman trained to work with 11,000 volt cables. So for a 16,000 foot run 8 BPL repeaters are needed.
At the customer's pole transformer a bridge will need to be installed to couple the signals from the 11,000 volt line to the 110 volt line (imagine what would happen if the bridge failed and your sockets had 11,000 volts!!).

However the math is worked, there is no way they can implement this vast array of expensive equipment in rural areas with any hope of meeting the alleged pricing.

The existing DSL broadband technology is proven and could be provided to almost everyone who has a phone, the barriers are political not technical. The solution to universal broadband lies in ensuring the phone companies serve all of their customers equally. BPL is a broken and polluting technology that is a pure distraction to the objective of universal broadband.

if its a decent brand of cable with good connectors its probably not worth shortening it. you will reduce the loss by about 50%, but the loss is probably low enough that it doesn't matter anyway.

How does the wrong load impedance comes into existence?

Is it not caused by the mismatch?

The mismatched impedance rolls down the transmission line to the transmitter and VOILA I have a 'wrong value' of load impedance. So, my amplifier or rig, with a predesigned range of tuning range, may now be operating off the designed load line.

Now, my understanding of transmission lines is that the mismatch at the antenna causes a reflection. The root cause of these issues is the mismatch that produces the reflection. The reflection manifests itself in VSWR. The VSWR circle on my SMITH charts indicates the range and values of the 'wrong value' of load impedance.

The 'wrong value' of load impedance, the VSWR, and the mismatch are all one family!!

Message-ID: <v1ilhvoomasae2di70c92unqk6j1krpmvk@4ax.com>
Source record: 112216

I just read the QST article on 60 meters and I have some questions.
The FCC said that 50 watts ERP is allowed and a half wave dipole will
be presumed to have a gain of 0 dBd. iI don,t think most hams will put
up a dipole for 60 , but will use existing antennas such as 30 40 or
80 meter dipoles.how would you calculate the ERP for these antennas to
be in compliance with the FCC. In my case I am able to tune my 30
meter rotating dipole on 60 meters. this is a 1\4 wave on 60 so what
are my requirements for record keeping.

Hey, that's cool. Been a ham for 46 years, made it through Air Force technical school, got a BSEE degree, and spent over 30 years doing circuit design without ever once coming across the term "impedor". And there it was, right in the IEEE dictionary. This newsgroup is sure educational!

Some confusion disappears. Some additional confusion arises. It should
be recognized that replacing a V/I impedance with an impedor is a shortcut
and doesn't necessarily represent reality. Math models certainly do not
control reality. For instance, ghosting is not the same in the two cases.
A TDR will not give the same results.

> Is it not caused by the mismatch?

Yep, the mismatch causes reflected waves which, in turn, cause the wrong load impedance. It's easy to see in the following thought experiment.

200W source---one second long 50 ohm lossless feedline-----open

The source will output 100V at 2A for two seconds from key down and be perfectly happy. The "wrong" impedance arrives exactly with the reflected wave after two seconds. The center of the steady-state SWR circle is the "right" impedance and therefore will not exist after two seconds.

Source record: 112125

My field rig is an FT-817, with MFJ-971 tuner. Antenna is a 40M
extended double zepp Slinky with 30 ft of 300 ohm twinlead.

On 60M, I easily tune SWR down to 1.0. Power shows a full 5 watts on
FM when I test.

Am I radiating almost everything the radio is putting out? Or could I
still be having big losses in the tuner? How can I test it?

Some have emailed me personally, and we have pretty much agreed on these two points(even Roy agreed with these, if you read his posts here):

1. Two antennas (also called transducers) placed close together actually can be considered a transformer, albeit a very inefficient one.

So an antenna can be considered 1/2 of a full transformer, so i wasn't that far off from a semantics point of view.

2. An antennas input impedance will depend on the impedance or permeability of the medium it is radiating into. In other words, an antennas free space input inpedance will be different from the input impedance of the same antenna immersed in water.

This is of course with a completely water-proofed antenna.

I went on to point out that a toroid transformer of a specific turns ratio, wire gauge, and core geometry, will definitely depend on the permeability (impedance) of the core material for it's characteristics.

Alas, i'm just a lowly practical engineer and not a PhD in EM wave-propogation (obviously no one else here is either). But if a transformer depends on 2 transducers' abilities to turn V and I into E and H (and vice versa), and that this depends on the impedance of the medium between them....then to me, an antenna is in some way "matching" to the impedance of free space, 377 Ohms, even if the energy has been converted to a different form.

1688. Re: basic question about radio waves !!!!

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-20 19:27:16 UTC
From: "Nic. Santean" <nic@csd.uwo.ca>
Message-ID: <3f1aed0d@shknews01>
Source record: 112131

WARNING: long posting - but an interesting one I hope

MOTTO: I seems that bad books are worse than no books
at all.

My confusion (fuelled by that dubious paragraph)
was to believe that "first hand" generated electric
and magnetic fields - by a dipole antenna - are the
actual components of the radiated electromagnetic
emission.

Of course not ! The RF source applied to a dipole
generates a magnetic field and an electric field 90
degree out of phase (it is a capacitive antenna). If I
look at Maxwell's equations, I see that the components
of the radiated electromagnetic field are pretty much
in phase. So, where is the catch?

Well, I guess this is:

The cause of the "legitimate" EM radiation are the
accelerated/decelerated charges in the antenna.
The components of this EM radiation are an electric and
a magnetic field in phase!, which reinforce each other. This
reinforcement is responsible of the linear! decaying of the
two fields with respect to the inverse of distance (hence
propagation at great distance).

Note. The term propagation is highly misused. A
(say, electro-)static field still propagates, just that
it does it at a very short distance, given by a decaying strength
proportional to the inverse of the square of the distance
(this was a second misunderstanding I experienced).

Back to the antenna. The electric field "first hand" generated
by the antenna - when the two types of charges are at dipole's
extremities - is in sync with the RF signal applied to the antenna,
and it does "useful job" along with it (it accelerates charges by
"collapsing" over the antenna). The current flowing in the antenna
generates a magnetic field "in sync" with the RF radiation (with which
I identify it - it generates an electric field etceteras..). I would say
then that the dipole antenna is a "magnetic" antenna, since its magnetic
generated field is at the origin of RF emission. This is surprising to
me. Am I right ??

Here's a brainstorming question for your review: this "first hand"
electric field helps with the acceleration of electrons. However, it

is also a time varying electric field, hence it will create an in phase
magnetic field etceteras... Then, we spot a second source of EM
radiation. Does this mean that a dipole radiates two separate twin
EM signals, 90 degrees out of phase ??

Some sort of feedback on this is appreciated - since I do not have
a physicist to keep me honest.

Cordially,

Nic.

1689. Re: 60 meter ERP

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-20 19:28:45 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vhlrbirhonta2b@corp.supernews.com>
Source record: 112132

One way to do it is to download the free demo version of EZNEC from http://eznec.com. After going through the "Test Drive" tutorial, you'll know how to model your dipoles at various frequencies. I recommend modeling them in free space for simplicity. Because of the dipole's broad vertical pattern, the gain of one dipole over ground compared to another at the same height is very close to their relative gains in free space. So free space results for relative gain are valid for comparing dipoles at the same height above ground. Look at the relative free space gain of your antenna compared to a half wavelength dipole. Then you can calculate the ERP of the antenna as:

ERP = P * 10^(G/10)

where P is the power you're putting into your antenna and G is the gain in dB relative to a half wavelength dipole. Or you can estimate it from a table of numerical equivalents of dB, so

ERP = k * P

where k is the numerical equivalent of G, e.g.

G(dB) k
1 1.26
2 1.58
3 2.00

etc.

Unfortunately, there's no easy way to determine what fraction of your radio's power is getting radiated. Just about the only practical way short of modeling or an antenna test range is to compare your antenna to another antenna with known gain and efficiency, and even this can be difficult to do with any accuracy. "Slinky" antennas are pretty inefficient, so even if your tuner isn't losing much power, the antenna itself is probably turning a good portion of it into heat.

The good news is that the antenna isn't likely to be less efficient on 60 meters than on 40. So if you're making QSOs on 40, you should be able to do the same on 60. Just keep that twinlead dry if you want most of your power to get to the antenna.

Roy Lewallen, W7EL

From: radio913@aol.com
Message-ID: <1d15af91.0307201140.1c182d3d@posting.google.com>
Source record: 112136

Hi Folks,

Someone once mentioned the following to me:

"You can calculate field strength from power and distance according to this formula I found in an old broadcast engineering handbook...

e = 7 * sqrt(P) / d

where e = field strength in volts/meter, d = distance in meters, P = power in watts. Antenna is assumed to be 1/2 wave dipole."

I'd like to know exactly how this simple formula was derived.

Any info greatly appreciated.

Thanks,

Slick

Put the forward/reflected power meter on the output of the tuner. Then
calculate the losses in the feedline.

Look at the Moxon design on the W4RNL site- simplistic parasitic antenna
but when done correctly achieves very hi F/B reminiscent of a cardiod.

Maybe you missed this one also: "reactor - a device, the primary purpose
of which is to introduce reactance into a circuit."

If you buy 'resistor', why not 'reactor' and 'impedor'? Same concept.

I would like to know why Cecil, for instance, uses pulses, as in a TDR, in order
to argue a steady state point. Impedance is normally defined for any "impedor"

at only one frequency at a time. A single pulse, according to Mr. Fourier, can

be characterized with a component at all frequencies. So which frequency and
which impedance are you talking about, Cecil, when you change the subject from
steady state to the time domain?
Secondly, math models are descriptions. Their purpose has never been to control
anything. Moreover, no one except you, Cecil has ever implied that anyone thought
they were. Do I detect a straw man here?

You would do as well if you took 19 inches of wire with an alligator
clip and connected it to the ground side of your rubber ducky. It
acts as the other half of a half wave dipole. Just let it hang there, its
placement is not very critical.

Hi Dilon,

You sure have been lead down the primrose path. Your simple questions
deserve better, but you have to butt heads harder to shake loose
dearly held fantasies embodied in the melange of response littering
the threads.

If you have three Watts reflected, it came from the transmitter and in
fact never left it, it simply turned to heat. The meter is indicating
a condition, not forcing it. A fever thermometer in your mouth will
tell you that you have a temperature in excess of the surrounding
environment (a clear mismatch except for rare summer days) and yet the
thermometer is not responsible for your fever (Thoreau once offered
that we were more comfortable before the thermometer's invention).

If you pulsed your transmitter with a short enough pulse, then you
would have another rare example, a power that returns to the source -

literally. However, after the first cycle of any HF transmission (or even partial cycle) that opportunity is lost forever (until you key-up to offer another short-lived opportunity with the future prospect of another key-down).

You can use a circulator to heat a dummy load if you wish, or you could use a tuner to reflect that power back to the antenna. You may well wonder why a circulator was offered in the first place. Rhetorical gamesmanship is the answer which has nothing to do with offering any real solution to you.

Another Rhetorical game involving the addition of 100W reflected to the original 100W now being added simply avoids the obvious that if you could force such a condition, then your 200W would be completely reflected too (what's the point unless you are intent in building a black hole generator?). And then you could project, "can I add 100W to the 200W reflected?" The cautionary response would be "can your rig stand to take the reverse boxcars of a train of 300/400/500...1GW...1TW.... coming back at it?" With a shorted transmission line only one wave length long being pumped at 10MHz, the reductio ad absurdum would quickly pile up these powers in one second of key-down.

Is it any wonder the manufacturers nip this in the bud? The clumsiness of such rhetoric is revealed through the obvious example of you not having been blasted into a smoking crater when tuning into even a slight mismatch.

What can 3W do?

Take a christmas tree bulb and light it up. Now grab it in a closed fist. Your comfort level may allow this, maybe not. Want to force the issue? Break the glass envelope and do it again with rubber gloves (offered to prevent the rhetorists from chiming in about shock hazard). I dare say the smaller volume of that same 3W will definitely have your eyes watering. Want to force it further? Take that filament and coil it smaller to pin head size and apply it against a finger pad in your closed fist. Blisters may offer a means to insulate you after a short while. Still the same 3W, in the volume of your final's transistor junction.

Fortunately, transistors are designed to take the heat your finger blistered with. They do this by careful design of "Heat Sinking" which is what the body does when sweat pours. Heat sinks are a packaging issue that have ratings in thermal resistance. The standard thermal resistance for a TO-220 transistor (flange style case) sitting in the open air is 4.5 ï¿½C/W. This means that the surface temperature at the metal tab would be 13.5 ï¿½C hotter than ambient if it was supporting only 3W and doing nothing else (doesn't sound like your situation at all does it?). By this I mean that same transistor is presumably the source of the original 100W (which is NOT the power being absorbed by the transistor) and as a consequence, and through

inefficiency (typically in the 40-60% range for a simple design) it might offer far in excess of 200 ï¿½C above ambient very quickly before it suffered catastrophic failure. This is why there are heat sinks.

When that same transistor is butted up against a finned sink, it also suffers issues of impedance mismatch and energy transfer problems. The first tuner of choice is quaintly known as "bird shit" or thermal conducting compound, there are also modern gaskets that do this job, but they are not as effective, merely close. When this grease is properly applied and the tab mounted against the card that holds it, it will lower that original Thermal Resistance from 4.5 ï¿½C/W by 70% to 1.25 ï¿½C/W. That same 3W will now elevate the transistor case temperature by 3.75 ï¿½C - nearly 10 degrees cooler.

If you were to clamp that flange against a proper heat sink with fins oriented vertically (not horizontally) you would drop the temperature even further.

However, transistors do not operate at case temperature, they operate at junction temperature, and there is far more resistance between the junction and the case than there is between the case and ambient. Have I lost you yet? If we harken back to that same TO-220 and ask what the Thermal Resistance is from junction to ambient, we would find it is 65 ï¿½C/W and the temperature for 3W is sufficient to boil water at the junction (remember that blister for the small coil of filament against the finger pad?). Now add the efficiency lost to heat to generate the original 100W!

This is where we get into catastrophic failures because that heat alone (the inefficiency of generation) is high enough to melt the junction's connections ... open circuit. Obviously TO-220's are not used in a single package, without heat sinks, to source your 100W, this is simply a means to illustrate the discussion.

When you are pouring the coals to the antenna and the wind breaks it presenting a fully reflecting load (the pits); you now have a zero efficiency situation at the finals. Where they roasted along at a marginal 200 ï¿½C, they quickly climb in an attempt to support heat capable of melting junctions and connections. You will notice that such advice as "your source does not dissipate reflected power," suggesting that you are safe, comes free and without warrantee for very good reasons. No one is going to foot the bill of your rig needing a new finals deck, and they will laugh at you to boot.

Does 3W present any hazard? I dare say absolutely no one will warrant their advice to that either. :-)

The reason (from their being burned before) is that no situation is comparable to their own or any other for that matter, and your rig may indeed be running with exceptional heat problems where 3 more Watts begins what is known as Thermal Runaway. Watch them rock on their rhetorical heels if you ask for this warrantee.

One very simple and telling example is back at the application of that luxury item called bird shit. This single point of interface, when performed incorrectly leads to more failures than all other mishaps combined. When replacing finals, this step is often taken for granted and the Amateur is often inclined to put on too much. This is death by fire, and it often arrives quickly. This is because the same Amateur is also unaware of other provisions of correct mounting that quickly increases the Thermal Resistance several fold (easily double, triple or worse) at the most critical interface = connecting to that lifeboat, the heat sink.

Well, perhaps too much explanation, you can certainly survey the other postings for their entertainment value in the form of cut-and-paste theory or equipment operator myths.

So I can change my reflected power, or SWR by adjusting my Pi-net
output?

I have never seen either one change when changing my load and tune
controls.

Thanks for taking the time to answer my questions. Its too bad a
newbie with a few simple questions can't ask them and get answers to
them. 99% of the answers made no sense to me. But I guess if they
did, There wouldn't be reason for me to ask my simple questions?

I have several friends in the "corn & wheat belt" of
Iowa and Nebraska. (I broker farm equipment)
All of them have internet access, either via traditonal
dialup or some who have DSL via telco fibre taps
in the trunks that run btwn the cities. Wireless BPL
would not be a seller. (one enterprising customer
in Ohio I know has set up his own wireless LAN that
covers a good chunk of his 4000 acre farm. He can
surf the web on his laptop while inside the cab of
his aftermarket A/C equipped John Deere 9000
Series Combine

> In reality, if the BPL lobbyists succeed, they will immediately focus
> on the wealthy suburban markets that are profitable (and already have
> cable and DSL) and ignore the rural areas.

Very true! Suburban customer and the VERY lucrative
College Campus market(s) are the real target
of this technology.

> The existing DSL broadband technology is proven and could be provided
> to almost everyone who has a phone, the barriers are political not
> technical. The solution to universal broadband lies in ensuring the

> and polluting technology that is a pure distraction to the objective
> of universal broadband.

The problem is there is one person at the FCC who
has known connections and investments into numerous
telecom corporations. His name is Michael Powell.
Get the big picture? Powell is to the FCC, what Murdoc
is to mass media.....

For an example of what I mean, go to the link below for more info :

Good... hold that thought.

>In the first case, reflections are the *CAUSE* of the
>impedance that burned up the transmitter.

Correct; and the values of R and +/-jX that the transmitter sees are
calculated by considering the reflected voltage and current waves.

So now we have two cases, one where reflections happen and one where
they can't. The transmitter suffers exactly the same problem in both
cases, entirely because it sees the same wrong value of wrong load
impedance.

"Reflected power" simply doesn't enter into it.

That's the whole point - the *only* difference is a conceptual one that exists inside your mind.

It has no reality out here in the physical world of measuring instruments and engineering, which is the place where the 1625s live (and sometimes die).

1707. Re: How was antenna formula for uV/Meter Derived?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-21 00:02:53 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vhmbdlen3p3g6b@corp.supernews.com>
Source record: 112150

Well, let's see. We can start with an isotropic antenna, which distributes its power equally in all directions. I did that one three days ago on this newsgroup, in the thread "Theoretical antenna question". The result is that the power density from an isotropic source at any distance r is

PD = P / (4 * pi * r^2)

where P is the total power radiated. Power density PD will be in watts/square meter if P is in watts and r is in meters.

In the far field, the field strength E from any antenna is sqrt(PD * Z0), where Z0 is the impedance of free space, very nearly 120 * pi ohms. E is in volts/meter if PD is watts/meter^2 and Z0 is in ohms. Substituting in the first equation gives

E = sqrt[(P * Z0) / (4 * pi * r^2)] ~ sqrt(30 * P) / r

So that's the field strength from an isotropic source. In free space, the power density from a dipole in its most favorable direction is 1.64 times the power density from an isotropic source at the same distance. This is the dipole's directivity which, if it's lossless, is the same as the gain (2.15 dBi). You can find this derivation in nearly any antenna text. So the field from a free-space dipole in its best direction is

E = sqrt(1.64 * 30 * P) / r = 7.01 * sqrt(P) / r

The 3W you measured was/is at the transmitter end of that feedline, it
could have been 30W at the load, but the feedline burnt up 27W as it
came back (it also burnt up the same proportion of that power going
forward). One of the truisms of measuring SWR is that a lossy line
will make the worst of load reflections look better.

In a sense you could say that a lossy line is cooling your
transmitter. Think of it as a remote heat sink. ;-)

SWR can be thought of as being derived from an equivalent lumped load
attached directly at the antenna jack (it is) or as from the long
system variable extended across space and storing energy (it is). You
should judge the character of an answer as needing to respond to BOTH
views in proportion to actual circumstances. Neither is independently
correct to the exclusion of the other (and this is why some discussion
devolves into pulses).

Hi Dilon,

Sometimes that is because they expect you to reference Google's archives of yesterday's posts. The problem there is that same archive is full of the same baloney offered to the last one they expected to reference the archives. Others will sometimes offer a significant search term that leads to a lengthy treatment quickly - the remainder don't have a clue and insist on proving it the hard way.

Finding real, actual data, experience, or theory is as rare here as it is anywhere when the price is nothing and the cost is high. Through "lurking" (reading, but rarely jumping into the game) over an extended period, you get to read personalities and observe personal weaknesses. If you looked back up the chain of responses and side threads, you should observe some correlations to answers offered in good faith (even if they were less than eloquent, a bit off the mark, or lost themselves).

Rarely is one blown off for simply being a newbie, but if anyone marched in here saying "I don't know how this works, but I can prove it ain't the way everyone says" - expect fried critic for dinner.

By-the-by. I noticed you referred to tube equipment along the way, or simply took up a ride with strangers (dangerous habit). Tubes exhibit the same problems with heat as transistors do. As this topic is hardly closed (if you lurk or participate, you will see your same question offered again); you should observe how denials emerge where a tube is somehow immune.

The proper expression would be tubes are somewhat immune and in fact are far more survivable than some transistor sets facing the same mismatches. Tubes also have a vastly larger surface area (of the plate) and thermal mass which offers much more resilience (the small junction meltdown happens faster) and they glow cherry red to prove it, as red as any carbon resistor flickering the guts of your rig with surplus calories. You can recognize these veiled offerings of proof of there being no way a transmitter suffers from reflected power in that they talk about everything but the obvious inferno. Having that larger surface area or mass also presents a problem though. It also comes with a larger distance from any way to sink the heat except through IR radiation and very little heat conduction (a lot is left up

to forced convection). In this sense, the Thermal Resistance is huge, and the consequent failure is found in plates that melt or grids that sag through heat expansion to the point that they short out to other internal elements. My buddy's amp got so hot that the solder connections to the socket pins of the tube (not the socket connector it plugged into) dripped to the chassis pan and opened the filament path.

If you read the dialog across enough time, you will observe that such discussion is avoided so that any particular scribbler does not leave a trail of admission to a fine point of Thevenin's theorem.... I will leave such mysteries of the inner circle to other threads. ;-)

This last is probably more your problem of obtaining a straight answer than any other source.

Do steady-state signals obey one set of laws of physics and pulses
obey a different set of laws of physics? You seem to feel so but
I just don't have that much faith!

The useful steady-state shortcuts have developed into a religion that
has no place in science. I am not opposed to steady-state shortcuts.
I am opposed to the steady-state religion that has evolved based on
faith. "Have faith, there is no such thing as reflected waves."
"Have faith, photons can be exchanged between equivalent inductors
and capacitors in a transmission line so they move sideways at less
than the speed of light instead of lengthways at the speed of light."

Particle physicists would really be interested in any proof of that.

"Have faith, a V/I ratio is identical to a physical impedance because
a source, with an IQ of zero, cannot tell the difference." "Reflections
completely disappear the instant that steady-state conditions are reached."
There are many more faith-based characteristics of the steady-state model.
These are just the ones that come to mind.

One more example of religious faith-based physics. The three watts of
reflected power that came from the transmitter and was rejected by the
load, never left the transmitter? This bears a distinct resemblance to
the virgin birth.

>with 11,000 volt cables.

All utility repair maintainers ("linesmen") must be trained and
qualified to work with primary voltages (11,000 V in your example).
There are special tools ("hot sticks") which they use daily to work
such open lines live, and they have no hesitation to pull the fuses
and work them "cold" if need be. Even after they pull the fuses and
ground the lines, they still use the "hot sticks" which are designed
specifically for the hardware in use.

Transmission voltages (34 KV and up) are something else. Those are
never worked hot.

(As the Portland General Electric channel on my scanner chatters in
the background.)

But you are 100% on point as to what is needed and what the
utilities are liable to do.

The transmitter possesses an IQ of zero. Hopefully, yours, mine, and
others exceeds that zero value. The goal is understanding. The goal
is (hopefully) NOT a reductio ad absurdum.

> "Reflected power" simply doesn't enter into it.

If you don't care about the facts, reflected power doesn't enter into it.
But if you are trying to understand the physics, certainly the reflected
power enters into it. If you don't care about understanding physics, by
all means, go with your steady-state shortcuts. But please don't try to
talk all the people who are trying to understand the physics into just
accepting your steady-state religion on faith.

1718. Re: Question for Roy Lewallen

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-21 01:27:59 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vhmgd7kcrnt814@corp.supernews.com>
Source record: 112161

It's important not to confuse the sort of pulses or steps used in TDR with transient sine wave conditions.

It's perfectly valid to derive the sinusoidal steady state conditions on a transmission line by looking at the transient conditions that occur from the time the source is first turned on. And because of the transient nature of the signal, the most practical way to approach this analysis is in the time domain.

TDR also (obviously) involves time domain analysis. But it's quite different. Sinusoidal transient analysis assumes a sinusoidal source that stays on once it's turned on. But TDR involves either a pulse type source that's off when the pulse reflection returns, or a step type source that provides a DC step to the transmission line. In this case, the source voltage is a stable DC value from the time of the initial step. In the case of the sinusoidal source, the source voltage continues changing while the transients are propagating.

In both cases, the sum of all forward and reflected voltages or currents have to sum to the correct values at all points, and this knowledge can be used to derive various wave components. But the results and some of the methods can be very different for the two cases. For example, when a reactive load or impedance bump is present, a simple reflection coefficient can be calculated for the sine wave, based on the reactance at the sine wave's frequency. The reflected wave will be a simple replica of the incident wave, altered only in phase and amplitude. You can't do this with a pulse or step; a reactive load changes its shape, defying a simply defined reflection coefficient. (Some confusion arises because of the use in TDR of a reflection coefficient, usually denoted rho. It's the same as the magnitude of the sine wave reflection coefficient -- but only if the anomaly or load causing the reflection is purely resistive and a constant value from DC or a low frequency up to the equivalent maximum frequency contained in the TDR pulse and viewable with the TDR system. With some TDR systems having equivalent bandwidths of over 50 GHz, this can be an onerous requirement.) Another important difference is what happens to a returning wave when it reaches the source -- reaction to a source that's off, at a stable DC value, or at some point in the cycle of a sinusoidal waveform is different.

TDR is a very valuable technique, providing important information and illuminating insights about transmission line phenomena. But great care has to be taken in extrapolating TDR observations to what happens in a sinusoidal transient or steady state environment. As readers have seen, I'm very wary of explanations of sinusoidal phenomena, either steady state or transient, that depend on drawing parallels to TDR results. You

should be, too.

RK,

Don't know if this is really about Shortwave; may be the interference
that it can cause to Shortwave reception.

But if you have your facts right then BPL would do little for our
rural communities but would do some major harm to radio reception in
Urban Areas.

While I would love a broadband connection out here in the woods. I'm not willing to sacrifice the spectrum. I'll just stick with my StarBand satellite Internet.

Not if it contains random noise and all waves contain random noise.

> TDR is a very valuable technique, providing important information and

Why? Does a TDR obey a different set of physics laws than sine waves?

It might be of interest to note that old time video amplifiers with peaking coils sometimes caused ghosts on the screen that were indistinguishable from ghosts caused by reflections.

I think the steady state solution would be a lot more palatable if the analysis started at T=0, when you turn the source on. The extra step of seeing how you reach steady state makes the latter more "real". One could almost be convinced that there are no reflections in the steady state; problem is , there would be no other explanation for standing waves, and I can measure them with unambiguous instruments.

Oh Goody. Turn that info over to the FCC Inspector General and the U S Attorney General, because it is a violation of Federal law to be so involved and/or he is perjuring himself on the required annual Financial Disclosure form.

Because we had to sell my then-wife's AT&T stock when I joined the FCC as a field engineer, I have no sympathy for someone else who tries to slide by without such divestiture....if in fact it is happening.

You do have solid proof of that, right?

I keep wondering what laws of physics get repealed just as the system
transitions to steady-state. Do photons really start moving from side
to side instead of end to end? Do the standing waves magically sustain
themselves without any reflected waves?

> there would be no other explanation for standing waves,

May I suggest that you consider charge.
Consider how static charge can store energy in the capacitance of the line.
Consider how moving charge can store energy in the inductance of the line.
Consider how the charge moves to change the energy distribution within the line.
Do it for a pulse of charge; then for multiple pulses.
Consider what happens when the pulses collide; consider pulses of the same polarity and different.
Do it for a step of charge; then make the step so long it looks like DC.
Do it for sinusoids.
Do it for opens, shorts and terminated lines.
Do it for matched, unmatched and disconnected sources (disconnect just after injecting the pulse, step or sinusoid).
Do it for sources at both ends of the lines.

And soon you will have an explanation which does not require waves travelling up and down the line to explain the observed voltages and currents of the standing 'wave'.

I have a video of a crew working on a 'hot' transmission line of several hundred thousand volts, using a helicopter. They don't shut down the big lines unless it's absolutely necessary.

>Shame on you for that attempt at obfuscation!

You are using that principle of impedance substitution whenever you calibrate your antenna impedance bridge using known values of resistORS, capacitORS and inductORS.

Of course *you* are aware of the difference in what's connected to the instrument - you have more information than it has. The only claim Bill and I have been making is that you cannot tell the difference from any *electrical* measurement made at a single frequency in the steady state... and those were exactly the conditions that burned up your transmitter, so the substitution principle is valid for this branch of the discussion.

That whole principle relies on the fact that, at the same frequency and in the steady state, the "definition of impedance" in terms of its electrical properties does *not* change. That's the whole point.

Visit the W4RNL site to look intot he different capabilities of NEC and miniNEC. If still available, Beezley's YO is tailored just for Yagi design and is very user friendly.

My three day use of EZNEC Demo has made EZNEC a
definite want. There is nothing that the demo
won't do, there are few differences, according to
the author. But the Demo has become my favorite
toy, and I am saving my pennies.

Reg has had that software on his site for years. It is called Dipole3.exe.
That is what I used to document my antenna for 60 meters.

Thanks Dale,
Yes I believe that YO is the application that would do the job.

The next trick is to try and get hold of Brian Beezley. There does not seem to be an updated email address for him and I can't find a site from where the software can be downloaded.

Any clues anyone?

Joel

Remember the UPS-220-222 MHz fiasco? FCC granted UPS that frequency range THEN UPS found it to be useless for their purposes. We still didn't get it back. Hams in Calif had set up the Condor net covering the state on 222 - all gone!

Maybe two dozen hams in Star Valley. 10K-foot mtns on east side;
9K-foot mtns on west. Virtually no HF workings here. Everybody on 2M
with repeater at north end at 8900-feet linked westward to Oregon and
southward to Henderson, Nevada through Snowbird Links. Repeater at
south end is 1,200-feet AGL for valley traffic. Another repeater in
Jackson Hole for traffic there with some of us able to access it.
Everyone else on the Internet for 'Round-the-world communications!'

Yes, soon you will have some mathematical shortcuts. But do mathematical shortcuts really cause photons to flow sideways between an equivalent capacitance and an equivalent inductance? Can you describe a bench experiment where photons are transferred from a capacitor to an inductor and back?

Drat. My DER-325 was scrapped out in Hong Kong. Would have loved to
have the GRC radio system on board. Maybe the fore and aft masts, too.
16 dipole elements on forward radar mast operating on 220 MHz with 300+
mile range would have been cat's meow for long distance work and on a
measly 300 kilowatts!!

> Sorry, that's not worthy of a reply.

OK, I'll answer it. No laws of physics get repealed just as
steady-state is achieved. All the steady-state model does is to
allow some mathematical shortcuts. (But it does not allow photons
to oscillate locally between equivalent lumped circuit constants.)

Some people apparently believe that those steady-state mathematical
shortcuts turn around and effect reality. Causing something happen in
reality by just thinking about a mental model is the domain of religion,
not science. The steady-state model does NOT effect reality. Conditions
on a transmission line are exactly the same whether the steady-state
model is used or not. Nothing magic, like disappearing standing waves,
happens at the instant steady-state is achieved.

Too many engineers believe in the primacy of consciousness rather
than in the primacy of existence.

The electrical properties *can* change and that's the whole point. The
electrical properties of a 50+j0 dummy load and a 50+j0 antenna are
almost completely different.

A transmission line can transfer photons. Can a lumped constant L-C
model transfer photons?

Ian, G3SEK wrote:
"A related topic would be the effect of tank circuit Q on bandwidth of HF amplifiers;"

Class A amplifiers are little used as HF finals, so in practical amplifiers current is only part-time.

Impedance of a parallel resonant circuit is high. Circuit impedance rises with inductance. Q rises with capacitance.

A Class C plate tank introduces a load on tube or transistor. It should waste only a small percentage of the power generated. It should have enough Q to linearize the output of the amplifier.

Terman says it is easy to show that the Class C tank circuit efficiency is: 1 - Qloaded/Qunloaded.

Loaded Q is the ratio of the circulating volt-amperes to the transmitted watts. If Q is too high, bandwidth is too narrow. If Q is too low, harmonics are high.

As Q is ordinarily high, the tank circuit impedance is higher than the load on the amplifier.

Impedance on the Class C amplifier has little effect on the tube or transistor loading. Output impedance presented by the transmitter to the load is determined in many cases by the percentage of the time the amplifier is switched-off.

voltages up to at least 765kv are worked hot in the states. there is a
helicopter company that specializes in this kind of work so that those lines
don't have to be shut down to do repairs. lower voltages like 115kv and
69kv are worked hot with fiberglass 'hot sticks'.

Cecil,

Try this out. For a line driven by a sin wave, there is a lumped parameter equivalent circuit with impedance R + JX for any line length and any termination. For a line exited by a pulse, this equivalent circuit is an infinite series with nuls at n/PW; there is no length of line where the line is resonant.

Hi Scott -

This is an interesting question.

A device like this SHOULD work, as the typical HT suffers tremendously from the lack of a "counterpoise." One only has to see how the typical end-fed half-wave HT antenna completely destroys a quarter-wave HT antenna, to get the point.

HOWEVER: I have tried using a quarter-wave stub (like the rattail), connected directly to the coax connector... and it seems to do almost NO good. I'm frankly at a loss to explain this.

I'm convinced that some of the short duckies are tuned to expect the counterpoise effect of the little HT chassis, capacitively coupled to a human body; so maybe there's a reason why they wouldn't benefit from a quarter-wave stub. But I have no theory why a full-sized quarter-wave antenna doesn't perk up more when a stub is added.

Maybe some of our computer modeling fans can propose an explanation.

Nic Santeen wrote:
"The RF source applied to a dipole generates a magnetic field and
electric field 90 degrees out of phase (it is a capacitive antenna)."

It could be an inductive antenna or a resonant (resistive) antenna, and the radiation fields, E&H, would still be at right angles in space, in the plane of the plane wave, perpendicular to each other and to the direction of travel.

Static fields distant from a current-carryinng wire are in a small way analogous. Imagine the current flowing toward you. Electric lines radiate like spokes radially positioned around the wire. Magnetic lines are concentric and make circles around the wire. At great diatance from the wire, the magnetic and electric lines are practically perpendicular and they are both perpendiicular to the direction of energy flow. Don`t make too much of this analogy, but it may be illustrative.

Borrow a copy of Terman`s 1955 edition from a library and study page No. 1.

Yes, but that's ALL it is - just an equivalent circuit. "Equivalent"
doesn't mean equivalent radiation. "Equivalent" doesn't mean equivalent
forward and reflected waves. It ONLY means equivalent NET voltage and
equivalent NET current at a point. It is a shortcut. It does NOT effect
reality. Past the net voltage and net current point absolutely nothing
is equivalent.

I didn't have to infer anything, Ian, those words in quotes are *your
quoted words*. Here they are again:

> That whole principle relies on the fact that, at the same frequency
> and in the steady state, the "definition of impedance" in terms of
> its electrical properties does *not* change.

That certainly implies that there is no difference between the electrical
properties of the impedance of a 50 ohm dummy load and a 50 ohm antenna.

They differ in that one of them utilizes a third more power. Your
problem proves that your analysis and the notion of power flow are
flawed.

> Each of these rearward-traveling waves contains |35.36V*0.707A| = 25 joules/sec

Waves are not 'containers' for a rate of transfer of energy.

> They superpose to zero. What happens to that 50 joules/sec of rearward-
> traveling energy?

As Timo and I have both said to you, it can be shown that that 50
joules/sec does not travel rearward.

> You have already admitted that wave cancellation is
> responsible for Pref1 being zero.

"Admitted" is a funny word for it.

> When waves cease to exist, they are forced to give up their intrinsic energy.

Waves don't cease to exist. They either do exist, or they don't exist.
V3 and V4 are not manifested to the left of the boundary when conditions
dictate they would be equal in amplitude and 180 degrees out of phase.
And of course neither wave is defined to the right of the boundary.

I am aware of how these vectorial fields look like ...

When I said "magnetic field and electric field are 90 degrees out of phase (it is a capacitive antenna)", I was refering that in any point in space, when the electric field peaks, the magnetic field hits zero; when the electric field drops to zero, the magnetic field change direction and peaks again in the other direction, etceteras. I said nothing about the spatial position of their vectors - which is a known, even by me.
I just said that there is a shift(!) between the sinusoidals.

My point is that a clean EM radiation has both fields in phase, which means that the scalar values of both vectors (electric and magnetic) change synchronously: when the electric field peaks, the magnetic field peaks as well, when the electric field hits zero, so does the magnetic field.

Therefore, I was saying that I suspect the superposition of two different EM radiation coming out from a dipole. These two fields do not necessarily reinforce eachother, but rather they create their own counterparts with wich they go along.

You must have misunderstood me.

This is more proof that the "transformer" action between two
antennas is highly dependant on the impedance of the medium between
them.

Roy, i don't mean to be an overly inquisitive laid-off engineer
with too much time on my hands, but how was E = sqrt (PD * Zo)
derived exactly? This is really the key equation.

Here's something else I'm wondering about. If you get an answer
of 1 uV/meter, does this mean that a perfect conductor of 1 meter
length placed in this field (polarized with the E field) will measure
1uV RMS if you measure the AC voltage on the ends? In the real world,
what sort of receiving antenna do they use to measure E fields?
Obviously, the recieve antenna will affect the measurement...perhaps
you want something broadband, so as not to favor a particular
frequency (a resonance on the receive antenna will throw off the
reading)? Perhaps something as isotropic as possible, so orientation
is not as critical. How does the FCC measure it, what equipment do
they use?

Oh, i think it's something like this:

Power density is in Watts per square meter, or V**2/(R*m**2).
If you accept that R = impedance of free space = Z0, then these will
cancel, and you are left with E = sqrt (V**2/m**2) = V/m.

You haven't answered my question so you have not earned the right to
set up a new straw man. Why does Pref1 suddenly go to zero just as
Pref2 arrives at the impedance discontinuity?

> As Timo and I have both said to you, it can be shown that that 50
> joules/sec does not travel rearward.

You have not presented an iota of evidence that Pref2 does not travel
rearward. Half of that 50 joules/sec comes from rearward-traveling Pref2.
Sorry, until you address that contradiction in your concepts, you don't
have any creditability on this subject.

You have repeatedly refused to answer this simple question: How does
the energy in the reflected wave from the mismatched load get turned
around? We know it possesses momentum so it does turn around. What is
your physics mechanism for explaining the change in direction of
momentum of Pref2?

>>You have already admitted that wave cancellation is
>>responsible for Pref1 being zero.

> "Admitted" is a funny word for it.

After months of denying it, you finally admitted it. Admitted seems
entirely appropriate.

>>When waves cease to exist, they are forced to give up their intrinsic energy.
>
> Waves don't cease to exist.

That's where you are wrong. Waves cease to exist when they encounter a
matched dummy load, for instance. Waves also cease to exist when they
are destroyed by wave cancellation. Light waves cease to exist when they
encounter a perfectly flat black surface. Your assertion is false.

>Remember the UPS-220-222 MHz fiasco? FCC granted UPS that frequency
>range THEN UPS found it to be useless for their purposes.

Amateur Urban Myth Number 1. UPS never applied for, and were
never granted, a license to operate a system on 220 MHz. The push
to "develop" that band was made by "Tio Carlos" Roberts, an ex-FCC
"fair haired boy" engineer who had stayed with the agency long
enough to talk them into giving him a grant to pursue a Master's
degree in Communications Engineering on a non-competitive basis - I
would have loved to get considered for that grant but I was not of
Hispanic heritage - and then dickered around as a rather ineffective
Bureau Chief until "the industry" waved money in front of him.

The ACSB equipment that he was hawking never worked, and UPS got
tired to waiting and went to The Big Emm and bought the existing
800 MHz system.

>We still didn't get it back.

By that time, other nation-wide entities (including the American Red
Cross) had applied for and were granted licenses for more conventional
(FM) networks nationwide.

The ARRL did appeal the takeaway through the courts but the courts
did not reverse the Commission.

>Hams in Calif had set up the Condor net covering

==========

Jack, you are perfectly correct. Of course the antenna doesn't need to be self-resonant. In practice it seldom exactly is.

It is only necessary that the load presented to the transmitter should be a pure (or near enough) resistance of the required value. Which is usually 50 ohms. But it can be any resistive value as the designer may specify. I have a transmitter which requires a 75-ohm resistive load. I have worked with it across the North Atlantic Ocean on 10 watts which PROVES beyond all reasonable doubt I am right. ;o)

IF THE LOAD PRESENTED TO THE TRANSMITTER IS PURELY RESISTIVE THEN, WHATEVER REACTIVE NETWORK OR CIRCUIT PRESENTS IT, BY DEFINITION, MUST BE IN A RESONANT CONDITION, REGARDLESS OF WHAT STATE THE ANTENNA HAPPENS TO BE IN.

The idea is so simple and obvious even the guru's can't get their skulls round it. ;o)

To hosts at Tea Parties in Boston, Massachusets - I take two lumps of suger with mine.

As is the Condor Connection. The repeaters are all in the 222-225
band. My understanding is that the inter-repeater links are all on
440 these days. One or two of the repeaters are down at the moment,
but most of them are up and working.

Most of the 222-225 repeater frequency allocations here in the SF Bay
area seem to be occupied by active repeaters. Some of them are
standalone, but at least half seem to be crosslinked to local 2-meter
repeaters.

> the energy in the reflected wave from the mismatched load get turned
> around?

That's a lie, and everyone here knows it. I've answered the question
every time it was posed. Timo answer it the same way I have. Energy
does not get turned around - it never flows to the left of the
discontinuity.

> We know it possesses momentum so it does turn around.

Must be the Royal 'we'.

> What is

That's an absolute fabrication. Revisionist history. I was the one who INSISTED that no power ever flowed back from the discontinuity. In fact you argued with me about it. You've got a major mental glich happening there, Cecil.

> Waves cease to exist when they encounter a
> matched dummy load, for instance.

The wave is transformed at a load. It doesn't simply "cease to exist". But I can see this is leading to another of your symantics arguments. You could avoid them in the future by using convention terminology. But I doubt you really want to avoid them. Seems they're the 'secret weapon' of the newsgroup warrior.

> > Methinks an antenna is just one part of an antenna "system" and that it doesn't
> > need to be resonant.
> >
and you are basically correct. an antenna is 'resonant' at only specific frequencies, even a small bit away from those frequencies it goes out of resonance but performance is virtually unchanged... if this weren't true the venerable 1/2 wave dipole and 1/4 wave verticals would only work on a single frequency... so we know from experience that you don't have to have an exactly resonant antenna.

note above i said 'frequencies'. this is to account of course for the resonances at multiples of the lowest resonant frequency.

likewise you can operate an antenna well away from it's resonances and it will still 'work'... theoretically an infinitely small dipole will radiate a field only a couple db weaker than a 1/2 wave dipole in free space... with the difference being that the 1/2 wave dipole changes the shape of the doughnut a bit, thus creating stronger fields in some directions and weaker ones in other directions. keep raising the frequency so that an antenna is longer and longer as measured in wavelengths and the pattern of these fields changes, but the total radiated power remains the same... so you can say that any antenna 'works' at any frequency and be correct.

The kicker comes when you start considering the whole system. while any antenna will radiate whatever power you get into it (minus a bit for resistance of the elements that gets lost as heat), the problem can be getting that power to go into it in the first place. this is where the 'resonant' antenna does help out. at resonance an antenna presents a purely resistive impedance to the feed line, generally this is a relatively easy load to push power into.... except of course in extreme cases of very low or very high impedances. as such it simplifies the requirements for the feedline and transmitter.

if a transmitter doesn't have to handle highly reactive loads, or extremely high or low impedances, it can be made much simpler and from easier to build or buy parts. if you have to design a transmitter to power a highly reactive load you have to be able to handle higher voltages or currents... higher voltages mean wider capacitor spacings, more insulation, and higher dielectric losses.. higher currents mean thicker conductors or expensive plating to lower resistance, and higher resistive losses.. both of those losses mean that in order to create the same radiated field intensity you need to generate more power in the transmitter to get it through the feed system to the antenna where it can be radiate. so while the antenna will radiate whatever you can give it, just getting it there in the first place

can be a chore.

There's no doubt, and certainly no disagreement from me, that the mutual
coupling or "transformer action" between two antennas is strongly
affected by the medium between them.

> Roy, i don't mean to be an overly inquisitive laid-off engineer
> with too much time on my hands, but how was E = sqrt (PD * Zo)

> derived exactly? This is really the key equation.

The power density is related to E and H fields by the Poynting vector, where

PD = E X H

I'm not going to derive this one -- you can find it in any
electromagnetics text.

In the far field in a lossless medium, E is in time phase with H.
Consequently, the magnitude of PD is simply |E| * |H|. The latter two
have to be RMS values for PD in watts; for peak values, you need an
addition factor of 1/2. Again in the far field, E/H = Z0, where Z0 is
the impedance of the medium. The definition of Z0 is generally defined
in terms of the permittivity and permeability of the medium, and the far
field E/H relationship follows from it. That's another one I won't
derive here, and that you can easily find in a text. In a lossless
medium, Z0 is purely real, making the math simple.

So, (dealing now only with magnitudes) given that PD = E * H and Z0 =
E/H, it follows that PD = E^2/Z0 = H^2 * Z0. Solving for E gives the
equation you're asking about.

> Here's something else I'm wondering about. If you get an answer
> of 1 uV/meter, does this mean that a perfect conductor of 1 meter
> length placed in this field (polarized with the E field) will measure
> 1uV RMS if you measure the AC voltage on the ends?

No, it doesn't quite work out that way, because of the triangular
current distribution on the 1 meter wire (assuming that the wavelength
is >> 1 meter). The "effective height" of a wire that's short in terms
of wavelength turns out to be 1/2 the actual length.

In the real world,
> what sort of receiving antenna do they use to measure E fields?

Near field E intensity is typically measured with a short probe. Far
field measurement is done with conventional antennas. In the far field,
once the E, H, or power density is known, the other two can be calculated.

> Obviously, the recieve antenna will affect the measurement...perhaps
> you want something broadband, so as not to favor a particular
> frequency (a resonance on the receive antenna will throw off the
> reading)? Perhaps something as isotropic as possible, so orientation
> is not as critical. How does the FCC measure it, what equipment do
> they use?

To my knowledge, the FCC doesn't do any measurements. Test labs doing
far field measurements typically use a conical dipole for the HF range,
and log periodic antenna for VHF and UHF. Although these are inherently
broadband, the dipole in particular varies a great deal with frequency.
So each antenna comes with a correction factor table. That's why EMI
measurement antennas, though simple, are expensive.

Some of the FCC Part 15 measurements I've been involved with are actually done within the near field, but are done with standard antennas nonetheless. Although the conversion from power density to field strength isn't entirely valid, everybody plays by the same rules. I think some of the FCC rules for safety now required for amateurs are also in this category.

I haven't seen quantitative near field measurements being done, just qualitative ones using a short probe.

>
> Methinks an antenna is just one part of an antenna "system" and that it doesn't
> need to be resonant.
>
> 73 de Jack, K9CUN

It doesn't. It only needs to be matched to the line. Or maybe I should
really say, the line matched to it. As far as "resonant", the
impedance could be nearly anything. If the reactance is tuned out,
it's resonant. A dipole, appx 70 ohms in free space. But make it a two
wire folded dipole, and you jump to nearly 300 ohms. But both are
still resonant. Make it a three wire job, and you jump to 450-600
ohms???.. You get the picture. It's still resonant. Many people prefer
a
dipole fed with coax, because it's "resonant" with an appx 50 ohm
feedpoint, and needs no matching. But it's not the antenna change, or
resonance, or lack of it, that would be an improvement. It's the lack
of a matching device and it's losses. And the already good match makes
the use of coax very low loss on most HF frequencies. On the low bands
, it's about as good as some ladder lines. Being the radio is usually
appx 50 ohm, it makes that case convenient, and naturally makes the
use of the "resonant" dipole seem superior to many other methods of
feeding a dipole. And it is usually. But it could have easily been
any other impedance. There is nothing etched in stone that says it has
to be 50 ohms. Many antennas won't ever be resonant the way they are
used. And some of these can have as much or more gain than any of
them. In the case of a dipole, to me, it would be foolish to replace a
coax fed single wire dipole, with a 2 wire folded dipole, fed with
coax and a 4:1 balun. I bet the single wire dipole would be more
efficient overall due to losses in the balun. Sure, small loses, but
they are there. :(It's all mainly a matching device/feedline loss
sort of thing. If you get power to the radiator, it will radiate,
resonant or not. MK

Every vertical "needs" the ground for its efficient performance especially at the low angles. Vertical dipoles and their elevated cousins are still "looking" out at the ground, farther waway and with a bit less of participation.
Wanna see dramatic display of salt water "ground" performance/contribution? Take your any verticaly polarized antenna and compare its performace between ground ground and salt water ground. You would see somewhere between 10 - 15 dB difference.

Yuri

Yes, most colleges (if not all) already have T-1 or T-3 lines which are networked through every building. I seriously doubt they would ever consider BPL technology because it would be a net loss of something on the order of 70% of their current bandwidth. Each student has more or less the equivalent of something like 5% of the total bandwidth available via BPL.. (these are only guesstimates, but they are based upon figures I have seen posted about BPL's bandwidth, it starts getting down to dial-up levels by the time it's been distributed to 2,000 users..)

Implicit in Roy's answer, but perhaps worth stating, is that the
result is for an antenna in freespace. If you are working with an
antenna over earth, things will be different because the energy is
radiated into a hemisphere instead of isotropically, and because of
interference and diffraction patterns, and absorption by the earth,
vegetation, etc. At some frequencies, absorption by things in the
atmosphere attenuates the signal, too.

Cheers,
Tom

Actually, the steady state "model" describes the observable aspects of
the phenomenon. According to a least one theorist, physics is a science
of measurement. Science is of course a study of observable phenomena.

Thanks for making that clear, Tom. I should also have emphasized that it's valid only in the far field, where the wave is essentially a plane wave with E/H equal to the impedance of the medium.

There are two quite distinct sources of ground loss involved with vertical antennas. You're talking about one, and Yuri is talking about the other. Makes for a lively discussion, but it's a lot like the blind men describing the elephant.

One type of loss is caused when it's necessary to connect one conductor of the feedline to the Earth. Current returning to this feedline conductor is equal in magnitude to the current flowing into the antenna from the other conductor, and it creates a simple I^2 * R loss flowing through the ground. This loss can be minimized by using a system of ground radials to decrease the loss resistance R near the base of the antenna, where the current density is highest. Another solution is to use a vertical antenna with a high feedpoint resistance. Examples are the half square, bobtail curtain, and half wavelength vertical. These antennas require very little feedpoint current, and consequently very little ground current. They can be very efficient with only a very simple ground system.

But there's another source of loss, encountered after the signal is radiated. When a vertically polarized signal strikes the ground, a lot of its energy is lost to heating of the ground. This is particularly true at low angles of incidence. The end result is severe attenuation of low angle radiation. Particularly for low angles, this occurs farther away from the antenna than a reasonable radial system extends. So you're stuck with this loss, unless you can physically move your antenna to a swamp or similar high-conductivity environment. Horizontally polarized waves react differently.

The demo version of EZNEC will show this quite dramatically. If you choose the MININEC type ground model, it acts like you have a perfect radial system. That is, the first source of loss I mentioned is zero. But the second is still there. You can simulate the effect of ground system loss simply by adding a resistive "load" at the antenna base. Compare the patterns of a vertical and horizontal, *to the same scale*, by superimposing them on a 2D plot, using different qualities of ground. You'll find it quite educational.

Apparently, neither have Ramo & Whinnery. But that's understandable,
given that the idea is entirely your invention.

> > What reason can you provide for continuing to beat your neice?

It speaks Cecilian, actually. You didn't notice the similarity in
technique? It was a response in kind to the exact form of the question
you asked.

> > I was the one who
> > INSISTED that no power ever flowed back from the discontinuity. In fact
> > you argued with me about it.

> I NEVER argued with you about that.

I cannot recall a single instance of you ever agreeing with anything I've written on the subject - including (V3 + V4) * (I3 + I4) = 0, and P3+P4-(2*SQRT(P3*P4)=0. That's wave cancellation my friend, and I posted these things at the beginning of this discussion. You've always argued with the validity of these equations.

> It was a mistake to try again to be civil to you.

When did that happen?

> > The wave is transformed at a load. It doesn't simply "cease to exist".

As I said, we're now in an argument over semantics caused by your creative use of terminology. "Cease to exist" in any case implies something which isn't true.

But back to the point, for what amount of time do the cancelled waves "exist" in order that they might then be able to "cease to exist"? If you say during the transient period between T0 and steady-state, then we're in agreement.

My SGC-500 amp says it will handle an SWR of 6:1 just fine.
If that is true, it means it will handle any impedance on
or inside a 6:1 circle on a 50 ohm Smith Chart. The great
majority of those impedances are not resistive.

1
Am I getting sucked into the bottomless black hole of transmission lines?
Yea, I care! If I want to test or tune my transmitter or amplifier and need a dummy, I use dummy load. When I need to radiate killer signals I use my Razor beams, but they are designed to have 50 ohm impedance and broad bandwidth (possible, been there, done it) no matching crap, no reflections (ok very small) and I don't give a Freak about nurturing reflections on the line. I hate reflected waves and I suppress their generation/reflection/travel and endless discussions about problem that nobody wants.

2
Huh? You haven't figured that SWR is bad for transmission lines?
All I want to know about transmission line that it doesn't have impedance bumps, keeps its impedance, that it has lowest possible loss and doesn't radiate or let the water in. (That goes for open wire feeders too :-)
Oh, color doesn't matter and it should be repulsive to chipmunks and other SWR ignorant critters.
Why is this endless argument about reflections going on? We know they are bad, we know how to eliminate them, so what's the problem? You love them so much that you want to keep them in your coax?
There are no reflections around this shack, only in the mirror of my ugly face after 48 hr contest.
OK hit me now that it is impossible to have reflectionless antenna-coax-tx.
My answer, yea, there are some (very little) and they are insignificant to me to worry about and lose sleep and hours at the keyboard. Ins't it like eunuch dreaming about sex? :-)

I quoted the evidence from Ramo & Whinnery. You just ignored it.

> I've answered the question every time it was posed.

But your "answer" is always a bogus non-answer, an empty mantra.

> Energy does not get turned around - it never
> flows to the left of the discontinuity.

According to Ramo & Whinnery, reflected energy does indeed flow
rearward from a mismatched load. That reflected energy possesses
momentum in the rearward direction and changes direction at the
impedance discontinuity. You still have not offered an acceptable
explanation for that energy and momentum turn around.

> What reason can you provide for continuing to beat your neice?

Your only response is a diversion. That speaks volumes.

> I was the one who
> INSISTED that no power ever flowed back from the discontinuity. In fact
> you argued with me about it.

I NEVER argued with you about that. You are back to your lying ways.
I would NEVER argue with a Bird wattmeter? You obviously have me
confused with Dr. Best. In fact, I published part of my article
saying that everything takes place at exactly the impedance discontinuity
and nowhere else. Having to lie about what I have said is just proof of
the weakness of your argument.

I'm sorry, Jim. I refuse to engage in a discussion at your chosen ethical and moral level. It was a mistake to try again to be civil to you.

> The wave is transformed at a load. It doesn't simply "cease to exist".

The energy in the wave is transformed from RF to heat by the dummy load. The RF wave certainly does cease to exist. You're not back to your phantom waves that last forever without a source of energy, are you?

> ZS6CBA

Joel,
I have no experience with anything other than AO which I have used
for many years. I purchased A.O. because it had the ability of
analysing any given radiator over different quality grounds and also
for it's ability to change the geometry of a radiator so that gain,
swr, F/B e.t.c can be optimised depending on your requirement.
Since I like to rig up different geometries of radiators on the
computor
before spending time on the outside experimenting I find it very
revealing when A.O. changes things around some what to achieve say
gain which I asked the program to do. It is also a great learning tool
because you can see
where major changes occur while the program runs that gives you
insights as to
what further changes you can present to the program and follow the
computors
progress as it changes geometries e.t.c.
I have just purchaes the A.O. Pro program which cost $300.
This program is the same as the std A.O. program except it has many
more pulses available e.t.c. which is extremely useful for accuracy
when dealing with very
close spaced wires, large arrays, together with the ability to use
terms beyond inductance and capacitance but also impedance which is
invaluable when designing
frequency agile antennas. Remember, that programs can only be seen to
be accurate when programs are run repeatedly with the increasing
number of pulses
until any increase of pulse numbers does not effect a change in
results.
If you are not dealing with large arrays or close spaced radiators

where the number of pulses available is a requisite for accuracy
then the standard amateur version should suffice.
As far as I am aware the A.O. program can achieve what most of the
other programs can achieve whereas most other programs cannot achieve
what A.O. can achieve which really tells the story.
Hope the above helps you to make the right descision for you
Regards
Art

The best possibility I can think of is that the impedance presented by the HT case/human hand and body is considerably lower than the impedance presented by the wire. If this is true, the body would get most of the current, and the quarter wave wire wouldn't get enough to make a significant difference to the total field. Another possibility is that coupling between the body and the quarter wave wire reduces the wire's current to a low level.

I recommend that anyone interested in HT antennas take a look at "An Investigation of 2-Meter HT Antenna Performance" by Ken Pierpont, KF4OW and Ed Brummer, W4RTZ, in the _ARRL Antenna Compendium_, Vol. 4. It looks to me like a good job of making some comparisons between antenna types. Unfortunately, they didn't try a single quarter wavelength wire, although they did try a 4-wire ground plane, and found a significant effect from it.

> to the transmitter. QED.

I suppose I am being picky Reg but shouldn't resonance be defined as
"totally" resistive load. An antenna can only be 'resonant' at one
point or frequency because movement from this point collects
reactance.
Fortunately it still has a 'resistive' component load which is the
PRIME requisite for radiation, whereas 'resonance' is not.
With the above being fully understood by newcomers a lot of the
mystery about 'antennas' and 'antenna systems' falls aside.
Cheers
Art

You really need to get your head checked. I am the person who first posted P3+P4-[2*Sqrt(P3*P4)]=0. It is proof of wave cancellation, the event you vehemently denied for about six weeks. And I agree that (V3*I3) + (V4*I4) + interference = (V3+V4)*(I3+I4) = 0. In fact, since you admitted that wave cancellation exists at an impedance discontinuity in a Z0-matched line, we have very little disagreement left. The only thing we disagree on now is how long it takes the two rearward-traveling wavefronts to cancel. I say it happens in a dt of time as dt approaches zero. You say it happens in zero time. Just how far apart are those two concepts?

> You've always argued with the validity of these equations.

BS! You argue loud and long, eventually change your mind, and then come back in a few days with The Big Lie - that is what you believed all the while. Anyone who has been following this discussion has witnessed you using that underhanded technique any number of times.

>>It was a mistake to try again to be civil to you.

Exactly what laws of physics completely change during the transient period between TO and steady-state? Photons start moving sideways instead of carrying energy up and down the transmission line???? More bafflegab!

Pref2(1-|rho|^2) obviously exists all the way from the mismatched load back to the impedance discontinuity. You have avoided explaining that momentum reversing mechanism like the plague. How do you get those photons turned around?

Ed,

In reply to your question on the technical requirements, (apologies in advance for the verbose response but would like to ensure that the implementation difference between European PLC/PLT and our BPL is understood by everyone).

In Europe BPL (PLC/PLT) is connected to the 220V (European voltage) at the transformer that feeds 100~200 homes. Typically backhaul from the transformer is a dedicated data line. European power lines are underground and the emission limits are lower (NB30) but there are still major interference problems. At NB30 emission limits PLC/PLT is good for about 900 feet.

Here in the U.S. our power system architecture is different with a transformer for 4~6 homes in the suburbs, in rural areas many homes will have individual transformers as the houses are far apart.

BPL is transmitted down (and emitted from) the 11KV medium voltage lines that go to the house transformers. 11KV lines have significant attenuation (and radiation) at HF.

The repeater issue has been "swept under carpet" as they are expensive and need a truck roll to install. The BPL lobby's focus has been to persuade the world that every socket magically becomes an Internet connection.

For details on a typical BPL repeater check;
http://www.amperion.com/products.asp

There are no details on specific repeater distances at the Amperion site, just a vague comment about data rates and latency. Latency will cause problems for VoIP and gamers (the ping numbers will be bad).

It is clear from the Amperion information that these repeaters are complex as they decode the data. Presume that power is somehow picked off the 11KV line.

The source for the 2,000 feet is here;
http://www2.arrl.org/news/features/2003/06/01/1/
"According to industry sources, data rates of up to 20 MB/s are possible for distances of up to 2,000 feet, and of up to 3 MB/s for distances of up to 4,000 feet."

The ARRL comments are for raw data rates under very ideal conditions, actual download speed shared by all customers will be about 35% of the raw data rate. The BPL systems both in Europe and the U.S. have symmetrical upload/download speeds which is puzzling, as would expect users to care more about download speeds.

If the FCC raises the emission limits, then the repeater distance will be greater. Suspect if they don't, the BPL operators will still turn up the power anyway and wait for complaints

Lowly only if you have any pretensions about being expert in the field of power measurement - and come to some other conclusion that is indefensible. If not, enjoy the hobby for what you seek in it.

Even equipment operators can put these issues to good use (or bad use in the sense that follows) if you participate in a Shoot-Out and use an amplifier with other than 50 Ohm output Z feeding an antenna with other than 50 Ohm input Z. Through hi-grading the 50 Ohm feedline to select that choice position along it for the Judges' Wattmeter, you can shave yourself 1 or 2dB advantage over the others through their ignorance of the Mismatch Error.

Of course, this is almost certainly a common condition and everyone is in the dark. So are the results, but what the hey, its only a game.

I offer the cutting line at "does it make more than 1dB difference" to offer a qualitative assessment. Personally, and as a belief, I rarely care about 3 or 6dB (more or less); hence 1dB is extremely liberal in their favor (and they rarely even meet that gracious low-ball). It is only the cut-and-paste theoreticians that demand their solutions are more accurate than nature can guarantee - and that it does make a difference. Such is the stuff of CFA and EH claims.

>before we can have a decent discussion about it?

Care to give an example?

> but what if its only a
>matching system to free space impedance? when there are reflections does it
>reflect or absorb? who started this topic anyway????
>

Hi David,

What if? What is reflecting? In this case BOTH the source AND the load. If you wish, we can jimmy up the load to present 377 Ohms and drive the error of power determination even higher (probably on the order of 50-80%). However, to this point two hours of work is sufficient to demonstrate this if anyone wishes to confirm my analysis. To this point a couple of days has revealed no data to have refuted my analysis. Denial is an option and opinion is free. Even at this steep discount none step up to the bench. I didn't expect anyone would anyway. ;-)

Dear Talking SGC-500,

Why do think I took the precaution of qualifying my statement with "or near
enough" ?

By the way, you would be most unhappy if your Tuned-tank or Pi-tank output
circuit didn't present your plate(s) with a near-enough purely resistive
load of the correct value. And would you mind asking your slave driver to
stop cheating with the aid of his 19th Century Smith Chart, please.

Hi Nic,
this a simple, intuitive and maybe completely wrong approach:
Let's consider a travelling EM wave at any point, distant from
antenna. Both the E and H fields change in time. IMHO the power
density at that point should be constant in time. When E=0, all energy
concetrates in H, which is either +Hmaximum, or -Hmaximum at that
moment. Vice versa, when H=0, E is + or - Emaximum.

Why should they change "synchronously", causing the power density at
any point swing from zero to "maximum squared" ?

> Therefore, I was saying that I suspect the superposition of two different
> EM radiation coming out from a dipole.
Be careful, the near field, approx. to 10x wavelength from an antenna,
may differ from the far field.

> 75-ohm model. All is based on assumptions. The only absolute value is SWR
> itself which does not depend on Zo or Z load but merely on their ratio. ...
Absolutely true. Any Zo is good. If we optimize a coax of a given
outer diameter with respect to maximum transferred power, we end with
Zo close to 50 ohms. If we do the same with respect to minimum losses,
we end up with Zo close to 75 ohms. That and only that is why 50 ohm
coaxes are preferred with transmitters (and transceivers) while 75 ohm
coaxes with receivers. Compromise value 60 ohms did not get into life.

From _Optics_, by Hecht: Equation 3.43 is the instantaneous flow of energy per unit area per unit time, i.e. the instantaneous Poynting Vector and is a cosine squared function. "It should be evident that E^xH^ cycles from maxima to minima. At optical frequencies, S^ is an extremely rapidly varying function of time ... Therefore, its instantaneous value would be an impractical quantity to measure directly. This suggests that we employ an averaging process."

The average power density (irradiance) is constant, not the instantaneous power density which is a cosine squared function.

> Why should they change "synchronously", causing the power density at
> any point swing from zero to "maximum squared" ?

From _Optics_, by Hecht:
"Since Ey and Bz differ only by a scalar, and so have the same time-dependence, E and B are *in-phase* at all points in space".

1807. Dipole connected to grounded receiver?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-22 11:49:49 UTC
From: Tom <tstimac01@yahoo.com>
Message-ID: <bfj8a7$7kp$2@ls219.htnet.hr>
Source record: 112060

I have one question about dipole connected to grounded receiver.

I've made dipole antenna. One "pole" is connected to center line of coax, the other to shield line of the coax. Cable goes down to receiver and connects with BNC. The BNC is (of course) connected to case. The case is grounded.

Can someone tell me, what is te purpose of the dipole if one of the poles is grounded? I mean, why i built two poles when one goes directly to ground!Shouldn't it be easier to build just a monopole? I'm puzzled....

Thanks in advance
tom

Watched an interesting program while ago on tlc or discovery about
electrocutions, power line workers in special helicopter were checking
lines
for bad insulators/leaks and were working on one section when the linesman
got electrocuted. Even with all safety equipment in use, he was knocked
out,
lost several teeth but survived.

Even with the power off these hv lines, there is some level of residual
power there
perhaps from static, the program did not get into details.

I would like to see how those cell antenna are installed on top of these
power towers.
Guess they use special crane to do it.

It would seem that the use of repeaters on the HV lines would require the
power line to be broken into isolated sections (RF-wise) where the repeaters
are located, with the 60Hz bypassed around the repeater. This can't be good
for reliable electric service.

if they are not properly grounded they can build up a static charge just from wind or passing clouds(thunderstorms or clouds that are building a charge separation even though they haven't actually caused lightning yet). they can also get charged by induced voltages from nearby energized lines, where the line you are working on runs parallel to another energized line it acts like a huge one turn transformer and if not grounded it can build up quite a high voltage.

>
> I would like to see how those cell antenna are installed on top of these
> power towers.
> Guess they use special crane to do it.

crane, helicopter, carry it up on your back, whatever it takes they get them up there... providing grounding and isolation at the base of the tower is the bigger problem. the control shack they connect to requires both AC power and usually a connection to a land based phone network. both of these need extra protection because if the hv line flashes over an insulator due to a fault or lightning the voltage at the base of the structure can get quite high, this can flash back over to the low voltage line and phone lines and get back into those systems. phone lines are easiest to protect by using fiber optics but power is another problem. One utility engineer i talked to at a lightning protection meeting described how a fault like that got into the distribution lines and blew the service drops off several houses down the road causing all sorts of collateral damage.

1814. AM/FM Reception on a new RCA/Radio Shack All In One unit DVD/CD,Cable,Aux Inputs etc.

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-22 14:42:44 UTC
From: Rev Tom Cox <rvtomcox@epix.net>
Message-ID: <E3cTa.9760$EZ5.3350629@news1.epix.net>
Source record: 112056

As he subject implies I purchased an all in one unit,with surround sound etc. The problem is I have yet to get even a static or buzz not to mention a real radio station on either the am or fm mode. The cheapos sent a small dipole antenna for the fm,(who wants a dipole antenna on their living room wall, and an obviously just as cheapo am loop antenna. I have now tried a $35 indoor antenna for am/fm that is under 12 volt power to boost signal. Still nothing works. The unit was in the shop for the dvd player and I ask them to check the function of the am/fm and the repair tag came back as all ok. I am surrounded by trees, but frankly all the other radios in the house work from my small portables to the large receiver that was replaced by the new unit.
Does anyone have any ideas as to what my next step should be? Assuming the am/fm function works then I am having trouble with the antenna, and an outside antenna is not out of the question but does not satisfy the am side. Open to all suggestions and Thanks for listening to a real neophyte in this area.

The power companies have already been using power line carrier repeaters
for many, many years. The repeaters are the bypass, not vice versa.

Nic Santeen wrote:
"My point is that a clean EM radiation has both fields in phase."

But in Nic`s preceding sentence Nic wrote:
"I just said that there was a shift (!) between sinusoids."

The two adjacent sentences seem contradictory. One respondent mentioned near fields. No need to complicate this issue now. Power was also inserted as an issue but its waveform differs from that of volts and amps.

A sinewave, volts or amps contains twice as many alternations as cycles. Each voltage peak, regardless of polarity, produces a positive power peak on each alternation in a resistance. Thus, the power is 2X the frequency of the voltage.

On a transmission line, the power flowing in each direction is forced to have current in the corresponding direction peak when the volts in that direction peak. The Zo of the line enforces synchronization..

In the free-space far-field, an optimally placed wire, 1-meter long, has exactly the number of microvolts induced in it as decribes the microvolts per meter of the field inducing the volts.

The r-f power flowing through the square meter containing the wire is calculated by squaring the volts per meter and dividing by 377 ohms.

Conclusion to be drawn is that 377 ohms is a resistance and the E and H fields induce power. Note, we have fields in space. There may be zero electrons in the space and the fields move merrily along. There is no current until a conductor is encountered.

Best regards, Richard Harrison, KB5WZI

isn't radio shack the 'answer store'??? have you tried asking them what the
problem is? with the cheapy AM loop antennas that come with those things
you should hear loud 60hz hum when it is close to the tv, if you don't then
most likely it isn't hooked up properly or the receiver isn't working. fm
depends more on how close to the stations you are, but if you have other fm
radios that work well with built in antennas and you can't pick up the same
stations on the supplied dipole something is probably wrong there also.

Go the store you bought your unit from. Spend
3.99 on a folded dipole cut for the middle of the
FM broadcast band (430-2385). Put it on the wall
in an "inverted V" configuration. Enjoy, you
will not notice the antenna 120 days later, they
are that inconspicuous. Spend no more than $50.
Buy stacked folded dipole antenna (150-2164
15.99), coax to feed from antenna to receiver, 2
75/300 ohm baluns (assuming your receiver's
antenna input IS NOT coaxial), wall bracket & mast
(if you do not stick the antenna in the attic).
The antenna is two of the folded dipoles,
constructed of aluminum tube, stacked at right
angles to each other to be omni directional. I
have owned and used both solutions for more than
20 years. I have sold, at Radio Shack the
solutions for 6 years to hundreds of customers w/o
return or complaint, and occasionally with
compliment.

Answer lies in the fact that any piece of wire, depending on its (electrical)
length in terms of wavelength is not anymore just "shorting" conductor. It is
an antenna, feedline or anything in between, definitely not just DC current
"grounding wire".
The other "pole" has the important function too, but that is another antenna
story.

Cecil, W5DXP wrote:
"That`s where you are wrong."

This argument has evoked plain statements, i.e., "When waves cease to exist, they are forced to give up their intrinsic energy." And, "Waves don`t cease to exist."

The statements need qualifications. Perhaps waves "cancel" without ceasing to exist.

My speculation is that two radiated fields which cancel don`t eliminate each other at all. They simply coincide out-of-phase, and their resultant is zero along an azimuth where cancellation of their effect continues. If we had a way to identify the vectors composing the zero resultant, we could prove them there. Separate modulation might be contrived to perform identification. The modulation idea comes from what happens as a null azimuth in a MW BC radiation pattern is approached. Carrier and sideband frequencies don`t cancel exactly together and it sounds weird.

On wires, it`s different. Connect same-frequency energy exactly out-of-phase, and you have a short circuit. In space, you don`t have an electric current. You may have zero electrons. You have only fields until you encounter a conductor.

Did I deny to let you live with your SWRed piece of wire? Be happy.

If my 7 el Razor, Quad Yagi log driven design is boring, and your piece of wire is exciting, may the SWR be with you!

Gee, what a revolutionary concept, let your transmission line do the matching for your doublet with open wire feeders. Yo everybody, tear down your coax fed beams, arrays, towers, just put up doublet and work the WAS in no time. Can you picture all those stupid contesters, serious DXers with decent antennas wasting their efforts to eliminate SWR from their feedlines? Yep, I can picture trying to use coax feedlines for matching kilowats to non-resonant antennas. Good for melting the ice in the gutters.

Be happy with your doublet, I am looking for "boring" killer antennas that can hear and work stuff that others can't. To me much more fun and challenge than your SWR endeavors.

Source record: 112068

I never saw the original posting, but it's been quoted enough that I think I understand the original question.

The E and H fields might very well be out of time phase near the antenna. And very close to the antenna (within a pretty small fraction of a wavelength), the magnitude of the E/H ratio will be considerably greater than 377 ohms if the antenna is much shorter than a half wavelength. However, beyond a wavelength or so, the E/H ratio will be very close to 377 ohms, and E and H will be in time phase. They'll be oriented at a 90 degree angle with respect to each other in space, but will be in time phase.

In the far field, the ratio of E to H (both magnitude and phase) are dictated by the medium, not the antenna.

Anyone interested in investigating this can do so very easily with EZNEC, even the demo version, using the near field analysis. It gives both magnitude and phase of E and H fields at any point in space for any antenna you can model.

> I thought they ate the RF without passing any to our precious environment.

They do eat RF without passing more than a negligible amount to our
environment. But they also convert the energy from RF energy to radiated
heat which is just as much of an EM wave as the RF wave was. The old
RF wave is destroyed but since the energy in that RF wave cannot be
destroyed, it must be converted. In this case it is converted to
an infrared wavelength.

The way to keep a resistor from radiating heat is to enclose it in
a heat sink in which case the heat sink probably radiates heat as
well as conducts heat.

Some waves cancel without ceasing to exist. But if the cancellation
is permanent, the waves simply cease to exist.

> My speculation is that two radiated fields which cancel don`t eliminate
> each other at all.

That is true, but that is not what we are discussing. We are discussing
permanent wave cancellation within the confines of a transmission line.

> On wires, it`s different. Connect same-frequency energy exactly
> out-of-phase, and you have a short circuit.

No you don't, Richard. Maximum current occurs at a short circuit.
The net current from two canceled waves is zero. The net voltage
from two canceled waves is zero. It is neither a short circuit
nor an open circuit to the canceled waves. It is simply wave
cancellation. To the canceled waves, it looks like both a short
circuit to the two voltages and an open circuit to the two currents.

It is the same thing that happens at the air to thin-film interface
in perfect non-glare glass when the incident beam is coherent.

If you get nothing on AM, not even at night, you are doing something wrong. Take another look at the instruction manual. Make sure the loop antenna is hooked up correctly, and that you don't have some wrong button pushed, as for instance, tape monitor; you could also be in some mode that mutes all stations that are not transmitting a digital ID. Can you take it back to where you had it repaired, and have them show you that everything is OK?

Tom,

The dipole is a balanced antenna, fed at the center. Stricly speaking, you should be using a 1:1 balun to connect to an unbalanced feedline. However, no great harm comes if you just connect it to the coax directly. DO NOT use a standard TV/FM balun, they are 4:1, and you are better off with it just like it is.

>
> The two adjacent sentences seem contradictory.

Well ! ? This is the whole point : they "seem contradictory" only
to those who believe that these fields are the actual components
of the SAME EM radiation ! Is this contradiction which made
me infer that actually there are two different EM radiations emanating
out of the dipole antenna : each of these out of phase varying fields
are the source of a separate EM radiation. These two separate
EM radiations eventually get superimposed at far distance (fact also
noticed in other two replies - this also explains why we are talking
about near and far fields).

What you just pointed out is actually what I wanted to prove.

BTW, this also implies that the dipole antenna is not an "optimal
transducer" - not even in theory. I leave this for other discussion.

Cordially,

Nic.

Thank you for the solution to a problem I did not realize I had. One of the pleasures of QRP is low power levels. One of the ways to get a greater bandwidth from a dipole is to make it a folded dipole. A great way to feed a folded dipole would be with a "TV" balun.

By now the math error should have become apparent to anyone bothering to
read through this litany of insulting inuendos and allusions. The
correct form is to take the product of the sums rather than the sum of
the products.
(V3+V4) * (I3+I4) = 0

AC6XG

The day before that I wrote:

I wish I could claim it was my model. Physics says that energy and
intensity are proportional. Hecht says that I = I1 + I2 + 2(I1 I2)^-2
cos theta. When cos theta is 1, and I1 = I2, I = 4I1. When cos theta =
0, I = zero. Energy is zero at interference nulls. Period. Note what
the intensity is at the nodes. You might try re-working the problem
taking that into consideration. Just some kindly advice, Cecil.

It was on 5/9/03 that I first posted the correct general form of the
irradiance equation:

I1 + I2 + 2*SQRT(I1*I2)*cos theta

> Exactly what laws of physics completely change during the transient period
> between TO and steady-state?

None. Funny you should think they would.

> You have avoided explaining that momentum
> reversing mechanism like the plague.

What momentum reversing mechanism?

Transmission lines have been around for about 150 years.
There was a variety of charts used to solve transmission line problems while Victoria was still in good health.
40 or 50 years later Smith drew some circles round one, marked it off in decibels, forward and reflected, and somebody attached his name to it.

In my exams I was stuck with a slide rule. Never used a Smith Chart myself.
I once had one in my hands handed out during a lecture.

==========
> BTW, it's not cheating! When I took my final exam in transmission lines

==========

Never heard of Kirwin. He sounds like a nice generous fellow. You got me wrong. The chart never cheats. But it does make a few 'naughty' assumptions. Unless the user is aware of them they will lead you right up the garden path as frequency decreases.

Thanks for proving my point. If you continually change your mind to
be correct, you can maintain your omniscient self image. OTOH, you
have not proved anything I said to be incorrect.

>>You have avoided explaining that momentum
>>reversing mechanism like the plague.
>
> What momentum reversing mechanism?

From _Optics_, by Hecht: "One of the most significant properties of
the electromagnetic wave is that it transports energy and momentum."

Are you ready to change your mind yet one more time and admit, contrary
to your previous assertions, that EM waves transport energy and possess
momentum?

Let's stop the debate over who said what (long before you even started
posting to this newsgroup). Please pick one point of technical disagreement
that you think exists between us and let's discuss it rationally devoid
of your numerous diversions, ad hominem attacks, and falsehoods.

Well actually my story is a little bit different. I've spent 1 and half hour diging the hole and beating the pipe with the sledge hammer for another 2 hours in front of my building while listening my neighbours complaining.... all that just to finally have a good grounding.

Connected the ground to my receiver and realized that from now on my dipole is no longer "floating". One of its ends is now directly grounded through the BNC connection on the case.

So now i would just like to know can i disconnect one of the poles from my dipole and use monopole? Is maybe the trick in capacity between two poles? Is that the reason why i can't remove one pole?

Thanks in advance....
tom

> ceasing to exist.

In the case we've been discussing the waves in fact never exist, except on paper. This is because, for example, V3 and V4 cancel at the very point at which they would begin to propagate. Cancellation precludes their existance because they cancel for any time element (after the transient period) and for every spacial element one can enter into the equation. Contrary to what has been suggested, they do not first appear and then subsequently disappear. Waves cannot just "cease to exist" for the very same reason that energy cannot cease to exist.

It may be somewhat easier to see this when we consider that each boundary can be viewed as a radiator, or re-radiator. When a wave impinges upon it, the boundary conditions and the nature of the incident wave determine how waves will be re-radiated from it. With a wave impinging upon the boundary from one direction only, we would have one outcome. With two or more waves impinging upon the boundary, we may have a different outcome.

You have answered your own question. If all the other radios work...to some degree. And the new one does not...at all. The new one is broke.

As for checking out the AM/FM at the shop. This could mean this to 'some' It lite up..it works.

Just don't try to use in on 160m. I put one on a network analyzer once, and looked like it would be good down to 40M. And you do mean QRP! That's #30 wire in there.

>W7TI

It's not holding by four holes, but by being screwed by the jacket.
Screwing the connector body onto the coax jacket provides weather proofing and mechanical "connection" between the cable and connector. What you did is to expose the watersucking braid to rain and braid will eventually break off at the junction of braid.solder/braid (tiny hair wires). If you never use the coax outside and don't rock it, you might be OK.
But can you picture "horrible" impedance jump because of your action? Cecil will never forgive you!
Kinda we were all stupid for all those years doing it the other way? :-)

take it back to the store and demand a refund. your unit is not
working. fm reception may require an external antenna of some sort
but there should be a ferrite antenna built-in to the unit for AM.
unless you're living in the middle of the mojave desert you should
hear SOMETHING on AM.

1) It NEEDS weatherproofing.

2) It produces an impedance discontinuity that is larger than that
produced by correct assembly. It will be more noticeable on upper HF and
VHF than 160 or 80 meters.

3) There is no strain relief.

4) If it meets your needs then only weatherproof it.

Well, that sounds reasonable and is why i asked what people used
on the receiving end for field-strength measurements. Would the above
be valid for wavelength << than one meter? Perhaps i'm totally off
because the 1 uV/meter might mean that one would measure the 1uV RMS
across 1 meter of the medium in question (377 Ohms for free-space, no
wire involved at all?)?

> measurement antennas, though simple, are expensive.
>

That's what i wanted to read, that they use a correction factor
table so that they can take out the natural resonance(s) of the
receive antenna. And it makes total sense that they would use a
different antenna for each frequency range.

The tricky part of making the correction factor table would be
that ideally, you would have an isotropic radiator that was perfectly
wide-band, and feed this with known input powers. This being
impossible, i would imagine that they might take advantage of the
reciprocity of antennas, and use the same antenna for both transmit
and receive, and then divide the correction factor by two, 1/2
correction for each antenna.

Perhaps the far-field measurements would require too sensitive a
field-strength meter? Or maybe it's just more convenient to measure

up close.

NC State University here in Raleigh has wired the entire residential campus,
RESNET, along
with the entire campus. A story in the paper reported that they ran enough
cable, including optical,
to go from Raleigh to Florida and back !

I think this bpl is a ploy to trash the bands so they can sell them off to
highest bidders
once the tv stations move to digital and leave the hf bands.

1860. 30 meter add-on for HF2-V idea

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-23 00:50:49 UTC
From: t_ashland@yahoo.com
Message-ID: <6e6aeba9.0307221358.7aef741f@posting.google.com>
Source record: 111954

I haven't tried it, but I thought why wouldn't a 23' foot piece of wire parallel to the HF2-V fed at the base work for 30 meters? I realize you might have to retune 40 and 80, but it sure would beat buying the 30 meter add on kit. Any thoughts would be appreciated. Anyone try any other 30 meter solutions with this vertical?

There is no broadcast television in the HF bands. Channel 2 is 54-60 MHz,
low VHF... but that part of the band (up through channel 5) is also within
the scope of BPL frequencies..

It's valid only as long as the length of the wire is << a half
wavelength (actually, << 1/4 wavelength for a single wire, half
wavelength for a dipole).

Here's the problem with that transformer concept again. A field is not a
voltage. So you can't measure it with a voltmeter. You can convert the
fields to voltages and currents by use of a transducer -- an antenna --
then you can measure the voltage and current from the antenna with
ordinary meters.

Good thing, too. Otherwise we'd all get electrocuted by the Earth's 100
volt/meter field. (And that's on a day with no storm nearby.)

The relationship between the fields, voltages, and currents is nicely
expressed by Maxwell's equations.

No, it's far field measurements that are more common. One problem with making near field measurements is that the near field varies all over the map with the type of antenna and the exact spot where you're making the measurement. And it's of no importance at all to anything very far away at all. I've only seen near field probing done to locate the source of a problem emission. Compliance measurements are usually done with far-field techniques, in or at least at the fringes of the far field. The "within the near field" measurements I'm referring to are HF measurements done at distances that aren't firmly in the far field. (The far field boundary depends on the nature of the radiating structure, and is nebulous anyway.) The FCC addresses this issue for Part 15 somewhat in section 15.31(f).

Yesereee!
K2KW and "team vertical" (Force 12) did some tests and measurements across the San Francisco Bay and found that using half wave vertical dipole and moving it from the salt water/beach boundary (0 dB reference) they would get 3 dB gain being 1/4 wave away from the edge, - 2dB for 1/2 wave and + 2 dB for 3/4 wave. Anything that is vertically polarized gets help from better ground, especially at the low angles in the pattern.
Claims of advertisers that their wundervertical needs no radials or ground are full of SWR!

I am trying to find some practical results of verticals being operated on the side of a hill. Anyone out there with experience?

There are lots of interesting and very good antennas for AM DXing. A box loop is very good. As are some commercial loops.
There is the K9AY and the EWE and the beverage on the groung antenne. The EWE is very interesting.

There is a club with a web page that is dedicated to AM DXing with lots of info at,

http://www.ircaonline.org/

Here is a good article on the EWE antenna for AM DXing at.

Humm...By antenna I assume it also means a radiator. This would
suggest
that a stagger tuned radiators would fall into the catagory discussed
above.
Now I have a problem with that statement, because I very much see it
as a transformer which is VERY efficient and not as you stated "albiet
a very inefficient one".
Can you explain to me how a stagger tuned antenna migrate into
inefficient radiators?
Seems to me that Thevenin's theorem would show this as being
incorrect !

I have NEVER soldered those damned holes. I remove the outer cover and
"pick" the braid all round. Then I remove the inner cover (center
conductor)and tin it. Then I fold the braid back over the remaining out
cover and then
screw on the adaptor (if any) onto the braid. Then I tighten the adaptor
onto
the body of the connector and tighten with pliers. Then I solder the center
wire

as usual. If there is any braid left I trim it off with a knife. This compares with
the "old" way and does not cause any more absorption--one ought to moisture-proof one's outside connectors anyway. Actually, in my experience, soldering
those stupid holes causes trouble of its own. With the braid soldered, the braid
suspends the feedline anyway, right? This means that the braid and the center
pin are in the same "room", as it were. All it takes is one eensy weensy wire of
that braid to get down into the center and short out the whole thing. By folding
the braid back AWAY under the adaptor (or under the rear of the PL-259 body) it isolates the assembly. Besides, it is easier to unsolder a connector and use it
again. It does work. and I have been doing it for over 30 years.

That's what some say. The energy is supposed to stop moving end to
end and just slosh side to side locally between the lumped constants.
They say that reflected traveling waves disappear when steady-state is
reached. I say such a disappearing act would have to be magic.

W7TI:

To do it right you gotta spend a little money and get the right tools.

To do it "right" you gotta buy a great big 200 watt soldering iron and pour the heat to it
for a only a short time. The coax braid is then soldered all around, not just tacked down
with a little surface solder at those four little holes.

Do it but don't skimp on tools, "Just do it right!"

> the very same reason that energy cannot cease to exist.

More bafflegab. An RF wave ceases to exist when it is dissipated in a dummy load. The energy cannot cease to exist and turns to heat but the RF wave, in a perfect dummy load, ceases to exist. Heat is not RF. A light wave incident upon a perfect flat black plane ceases to exist. The light waves that haven't exited the room you are in when you turn off the light cease to exist. Some light waves falling upon plants cease to exist in the process of photosynthesis.

From _Optics_, by Hecht: "Unlike ordinary objects, photons cannot be seen directly; what is known of them comes from observing the results of their being either created or annihilated."

When photons are created, their wave function starts. When photons are annihilated, their wave function ceases to exist. There is no such thing as preservation of photons. You really need to get yourself a better physics book.

EM waves cease to exist all the time but the energy in those waves cannot be destroyed.

When I worked for Dresser Industries in Houston in the 60's, some
of our SCADA systems sold to power companies operated over power
line carrier systems. As I remember, it operated on RF frequencies
below the AM broadcast band.

A web search for "Power Line Carrier" turned up 650,002 entries
including some for high speed internet access.

There's another one of your contradictions. "Cancellation (of two waves)
precludes their existance ..."??? How can two waves cancel if they never
existed? Once again, you are confusing cause and effect. You are asserting
an effect caused by itself. That won't fly.

There is nothing in calculus to prohibit those two wavefronts from existing
for a dt of time. In fact, for 100% wave cancellation to occur, the waves
must necessarily exist for a dt of time. One wave cannot cancel. Cancellation
requires at least two waves. Maxwell's equations contain partial differentials
for dx, dy, dz, and dt.

In the s-parameter equation, b1=s11*a1+s12*a2=0, s11*a1 and s12*a2 obviously
exist. Otherwise, b1 could not be zero due to their cancellation.

In the transmission line voltage equation, Vref1 = Vfwd1(rho) + Vref2(tau),
those terms obviously exist. Vfwd1 is not zero. rho is not zero. So Vref1
could never be zero without 100% wave cancellation of two existing waves.

You seem incapable of conceiving of canceling wavefronts that exist for only
a dt of time. I, OTOH, am completely incapable of conceiving of the cancellation
of two waves that never existed.

I suspect it might be the word "quality", or the absence thereof.

The high-quality silver-plated PL-259s seem to solder easily enough as long as you have a high-enough-wattage iron or gun. A small fixed-wattage, non-temperature-controlled soldering pen probably won't do the job.

The cheap nickel-plated ones can be a real hassle - the solder doesn't wet the nickel at all readily, and one can easily end up with a "cold" solder joint.

I've read recommendations that if you're going to solder a nickel-plated PL-259, you should take a file and rough off the nickel in the area around and in the holes, and on the adapter inside (if present). The brass under the nickel will take the solder somewhat more readily.

Ghosts live in the land of strong signals and good multipath. Several persons in my area of the world (the southern portion of the northern state of Delaware - the two smallest states in the Union) will point an antenna at Philly and another at Baltimore. They are not troubled by ghosts. Ghosts result from two, or more, signals reaching the receiver close enough together and in sufficient strength to become part of the picture.

Cross-posted to:
rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.policy,rec.radio.shortwave

It would be very difficult to achieve sufficient input to output
isolation to repeat on frequency so either do time division (lots of
latency) or translate to another band (most likely).

Guess these repeater units would be very vulnerable to any non
linearity that causes I.M. or harmonics from the output to occur at
the input frequency.

The more I think about this, the more convinced that the BPL lobbyists
have excellent P.R. and are first division bull shit merchants but are
totally and utterly clueless when it comes to R.F.

Expect a few systems to be deployed before the money folks from Wall
Street realize that BPL won't work. Trouble is that a few badly
maintained systems could trash the whole of H.F. during the next
sunspot maximum. Reminds me of the pager transmitter on the next hill
to me, wakes up once to twice a day and overloads my 2M equipment.

Yep - something about "doing it right", as Peter says also. Not just to ape the professionals, but because the "right" way is the one that's most reliable and won't let you down.

A lot of my ham training was in VHF portable contesting, where you and your friends are out on a hill for a weekend with whatever you brought with you... and nothing more. It quickly taught me that a little "quality" in the right places goes a long way toward making the whole ham radio experience much more enjoyable.

In that particular case, a lot of the spoilt weekends were due to connectors, of which there are dozens in a complex station. "Quality" involved assembling connectors properly at home, so they wouldn't fail up there on the hill - and after we learned that lesson, it all became a lot more fun.

But there's something else as well, beyond all the practical reasons: I actually *enjoy* doing ham radio well, with quality.

Perhaps more of us should come out and say that...

Anyhow, back to the PL-259s:

>The high-quality silver-plated PL-259s seem to solder easily enough as
>long as you have a high-enough-wattage iron or gun. A small
>fixed-wattage, non-temperature-controlled soldering pen probably won't
>do the job.
>
That's true, but DON'T BUY A 200W IRON - it's a waste of money!

* Buy a cheap hot-air gun from the DIY store.

* Use it to pre-heat the connector body until your regular little iron can easily melt solder on the connector body (not just a blob in the hole, but flowing easily onto the body).

* Take the hot air away, and quickly solder the connector with your regular iron.

It's quick, easy, low-cost, you get a "free" hot-air gun... and it produces a top-quality job.

I now use this method for all kinds of heavy-duty soldering, with
nothing larger than a Weller TCP iron.

A good point about removing nickel plating first:

>I've read recommendations that if you're going to solder a
>nickel-plated PL-259, you should take a file and rough off the nickel
>in the area around and in the holes, and on the adapter inside (if
>present). The brass under the nickel will take the solder somewhat
>more readily.
>
Inside the holes is the important place to remove the nickel. Ream it
out with a drill, or the pointy end of a triangular file.

Well, two identical antennas spaced a few wavelengths apart can
be considered a transformer, but very inefficient compared to a "real"
transformer with identical primary and secondary turns, with an
appropriate toroid core. This would be because the core material will
increase the magnetic flux density, and will increase the coupling
between the two windings/transducers.

Point is, the farther apart the antennas are, the less efficient
of a "transformer" they will be.

I'm not familiar with stagger tuned antennas, although the name
would suggest that it is tuned for multiple resonances, so that the
antenna will be broadband.

So can 4nec2. It's optimizer was based on the same principles as AO.
Furthermore it can (almost) automatically convert *.ant files to 4nec2
input files. (just specify your *.ant file as a 4nec2 input file).
Besides that 4nec2 is based on the nec-2 core whereas AO was based on
the mininec core, especially important when modeling 'close' to
ground.

> It is also a great learning tool because you can see where major changes
> occur while the program runs that gives you insights as to
> what further changes you can present to the program and follow the
> computors progress as it changes geometries e.t.c.

I would suggest to take a look at the 4nec2 'evaluate' option. With
this you can stepwise change one or more antenna, ground, load or
other dimensions and see what effect they have on far-field pattern or
other antenna characteristics.

> I have just purchaes the A.O. Pro program which cost $300.
> This program is the same as the std A.O. program except it has many
> more pulses available e.t.c.

4nec2 max is 5000 segments for XP systems, max 11000 segments for
none-XP systems

> As far as I am aware the A.O. program can achieve what most of the
> other programs can achieve whereas most other programs cannot achieve
> what A.O. can achieve which really tells the story.

I would be very glad to know what you think could be added to 4nec2 to
make it even better.

Furthemore it might be usefull to know the following is also possible:
- Switchable genetic based or traditional hil-climbing optimizer
- 2D, 3D graphical- and chart- display of near-field data
- Optional surface wave-data included in far-field.
- Sophisticated Smith-chart display when using frequency sweep.
- Interface to VOACAP propagation prediction freeware
- CAD alike geometry editor for starting modeler (however not usable
when optization is required, see help-file)
- Nec-2 aware or default notepad editor also usable.

One drawback might be the lack of a very comprehensive getting started and/or user manual, but you can always contact me in case of problems.

Please don't interpret this as an advertisement. Just as an attempt to share some private-made software with others interested in antenna modeling and/or propagation prediction.

Arie.

I hope you'll pardon me for amplifying this a little.

If you put X watts into the primary of a transformer and extract Y watts from the secondary, the efficiency is Y/X by definition.

If you put X watts into one antenna and extract Y watts from an antenna coupled to it, and measure the efficiency of the "transformer" the same way as you did the conventional transformer, you'll find it has lousy efficiency. Why? Because a goodly fraction of the power you applied to the "primary" antenna never gets to the "secondary" antenna because it's radiated instead. As far as the "secondary" is concerned, it might as well have been converted to heat.

If you look at the impedance of the "primary" antenna, you'll find an excess of resistance -- just enough, in fact, to account for the "lost" (radiated) power.

This isn't a statement about how well coupled antennas function as antennas, whose purpose is to radiate after all. It's a statement about how well they function as a transformer. Poorly.

> then you can measure the voltage and current from the antenna with
> ordinary meters.
>

I agree with you that the field is first converted by the antenna
before it can be measured.

But by definition, the E field is definitely related to voltage
potential.

Hugh Skillings' Fund. of Electric Waves: "Voltage from point 1 to
point 2 is the line integral of the electric field along any path from
point 1 to point 2. This is the amount by which point 1 is at a
higher potential than point 2."

Say PD = E^2/Z0 = H^2 * Z0. If you say the Power Density =
V^2/(R*m^2), and the R=Zo, then these will cancel, giving you E =
V/meter, which are the correct units. So here we are equating the
impedance of free space will a resistive impedance or load.

Roy, what do you think 1uV/meter really means in terms of how you
measure it? I mean, under what conditions must you have to measure
this 1uV/meter?

I'm starting to think that what this really means, is that an
exploring particle with a unit positive charge, when placed in a
electric field of 1uV/meter, will experience a change of voltage
potential of +1uV when it is moved directly towards an isotropic
radiator ("the potential of a point in space is the work required to
move to that point a unit positive charge, starting an infinite
distance away...potential increases as one positive charge is moved
closer to another positive charge" - Skilling).

> Good thing, too. Otherwise we'd all get electrocuted by the Earth's 100

I was going to ask you to define "far-field", and i thought maybe
people defined this as a number of wave-legnths away, but if it's
nebulous like a lot of RF topics, then i would certainly understand.

Hi,

I agree with the other poster who said most of the mechanical
strength is from the outer vinyl being screwed into the PL-259.

This method looks a bit too weak for me to ever try.

Get a Weller GUN. And make sure the tip is screwed in TIGHT!

It's not nebulous at all. There is no boundary fence in the ether with a sign saying "Here endeth the near field", but you *can* draw your own lines.

That is not at all unusual in physics and engineering, nor is it limited to RF problems.

In the idealized far field, the E and H fields are orthogonal, in phase and have a ratio of 377 ohms. At any finite distance, you know that you're not in the idealized far field, but until you come quite close to the antenna you can't measure the difference in any way, so ideal far-field conditions are a very good assumption. Coming closer to the antenna, you enter the transition zone where you start to see measurable and calculable deviations, but you can set an engineering criterion to say you're still close enough to far-field conditions (a 1 degree E-H phase difference is one example, but people can and do set different criteria for different purposes).

Equally, you can begin in the near field and work your way outward. You'll notice some strange behaviour of the E and H fields very close-in (all of which turns out to be completely predictable if you try hard enough) but farther out they get their act together and settle into their correct far-field relationship.

The lack of ready-drawn boundaries doesn't make any of those ideas "nebulous". They are exactly as clear - or exactly as nebulous - as the way you choose to think about them. There's still the same rock-solid physics underneath.

It seems we never have the time, money, tools or inclination to do it
right the first time; but, we always do it right the second time.

Unfortunately the second time is generally most inconvenient!

Thanks again for fine software Arie.
Things I would like to see is incorporation of terrain simulation with antenna design. Few zones of different "ground quality" (radials, sand, salt water) with linear and/or circular boundaries plus sloping terrain (contour profile). Example would be four square array on the sloping hill of sand some distance from the ocean. Verticals are very sensitive to the ground quality and terrain slopes/profile and this feature would be a great tool in quest for maximizing the performance of array by using the terrain features (enhanced F/B).
K6STI has Terrain Analyzer (?) I have never tried it, but I understand that he uses free space pattern of antenna and then applies the geometry and quality of ground. I can see that more true representation of antenna's performance is to tweak the design with real ground/terrain situation. Vertical antennas, where ground participation makes significant difference in the tuning of array, would be more closely modeled by using real ground rather than free space (who's got it anyway?) and then doing optimization with given ground/terrain situation. Enough challenge? I don't know of any software that would do optimization with participation of ground/terrain.
Thanks again!

I am not sure how to do this test.

The tuner has a 4:1 balun built in. Losses could certainly be in the
balun.

The coax terminators on the tuner do not use the balun. A separate
SWR meter will have coax terminators, requiring the use of a
standalone 4:1 balun after the meter, into the twinlead.

This will test tuner losses, but not losses in the balun.

I guess my follow-up question is, How do I test for forward/reflected
power in a twinlead feedline?

I have an RF probe; can that be used somehow?

Arie,
I remember when you first spoke of your program on this newsgroup
where I commended you for your sharing attitude. My computor was down
at that time but I do remember the many comments given , all of which
were good.
I really should have noted the facts down as it appears to me that
your program
offers much more than any program on the market and is a formidable
new height
that competing programmers will have to overcome.
Rest assured that I will be taking a closer look at your work since I
believe that the optimisation tool is a prime requisite of any antenna
evaluation program.
Best Regards
Art

> I hope you'll pardon me for amplifying this a little.
>
> If you put X watts into the primary of a transformer and extract Y watts
> from the secondary, the efficiency is Y/X by definition.

Yes Roy. The specifics of what is being discussed is all important
when looking at answers as well as what terms are being used to
measure 'efficiency' and to what ends.
As you are surely awawe I too look at antennas as transformers or
coupled circuits and thus the primary contributes very much in its own
way as far as radiation as does the secondary. Thus 'efficiency' as a
criteria of 'value'
is all important when using it as a term since as you point out it is
a ratio of two terms both of which have to be made very clear for the
term efficiency to be made clear
Thus in stagger tuning it is important to define your requirements in
terms of bandwidth (dual frequency radiation) or max gain (dual
radiators on the same frequency),the above bearing little difference
to old time receiver designwith multiple I.F. cans. It is in this
areana that I view stagger tuning or coupling
as being efficient in charactor. If I am incorrect in the above
assumptions I would welcome any correction from those well versed
inthe field.

Arie,
One more thing comes to mind, it would be desirable to be able to use insulated wires in models. Typically house electrical insulated wire has about 5% shortening coefficient. I think it would suffice to enter the shortening coefficient (can be obtained by measurement). I believe NEC4 can accomodate that and could serve as an example how to do it.
Also different material for elements within antenna, like copper (insulated) wire quad and aluminum Yagi elements.

That's it besides transducer for the brain to "see" the design in my head and optimize/model it in 3D :-)

Nic Santeen wrote:
"Therefore, I was saying that I suspect the superposition of two different EM radiations coming out from a dipole."

"Does this mean that a dipole radiates two separate twin EM signals, 90 degrees out of phase?"

The statements are from two different postings. Superposition says simultaneous voltages in a network cause a current which is the same as if the voltages acted individually. This is not rigorous, but it`s the gist.

A dipole gets its name from two (di) poles. However, current flows from one element into the feedline and out of the feedline into the other element. This makes current in the two elements in the same direction, if the dipole is not too long. The dipole works like a continuous rod with the radio`s resistance in the middle.

Point is, a dipole is a single radiator / receptor of radio waves.

Two fields are emitted and captured when a radio wave is radiated and received. The two fields are merely components, electric and magnetic, of only one wave (EM radiation). Radiation requires both components.

For the foregoing reasons, it is wrong to say a single radio frequency has anything to do with "two different EM radiations coming out from a dipole".

As for "twin EM signals, 90 degrees out of phase", the right-angle relationship is spatial, in the plane of the wavefront, and it is not between twin signals. It is between the lines of the E and M fields.

Richard, I think maybe he was referring to the MOM method of dividing a wire up into 'n' segments and assuming each segment is a small individual radiator. The radiation from each small radiator is vectorially summed with the radiation from all the other small radiators. Close to the radiators, the E and H fields can sum to being out of phase.

If you change his "two different EM radiations" to "N different EM radiations", then what he is saying might be more understandable.

:-) Sorry, Cecil. It's a fact.

>Cancellation
> requires at least two waves.

:-) Cancellation requires zero waves You can't have it both ways..

> Maxwell's equations contain partial differentials
> for dx, dy, dz, and dt.

Yes they do, and for any set of finite values of those variables for two superposed functions of equal amplitude an opposite phase, the solution is zero. You can write the functions for the two waves and prove they cannot exist.

> You seem incapable of conceiving of canceling wavefronts that exist for
only

I use the holes because I think it makes a better connection especially if the outer cover is properly "screwed" into the connector.

I found an old 100-W soldering iron, not gun, at a yard sale for 50 cents. I machined (filed) the tip so that it was no longer pointed but cylindrical so that the tip would just enter one of the four holes.

I hold the hot tip in the holes until the solder flows and "tins" the braid and the connector.

If needed I can use some non corrosive flux to make me think I did a better job.

You guys might want to try crimp style alternatives to the PL259. I have used them with no problems. They might actually have an advantage when connecting to coax that uses aluminum fail and not much braid.

See, I told you that hot air gun would be useful.

If he'd used one of those to strip the old paint off properly first,
they wouldn't be having to restore that Sistine Chapel after only a few
hundred years...

Yep. I use a half-round to 'grind' the rims of the holes down to base metal before assy. Then, using a WAY HOT, HIGH WATT iron -- not a gun -- I get onto and off of each hole with solder as quickly as possible -- making sure I `fill` each hole completely.

But, as another poster mentioned: A well-done PL-259 install always makes for a Very Difficult reclamation. HI!HI!

> As for "twin EM signals, 90 degrees out of phase", the right-angle
> relationship is spatial, in the plane of the wavefront, and it is not
> between twin signals. It is between the lines of the E and M fields.

It appears that I am having difficulties explaining this
"out of phase" business. Let me try once more:

Take a snapshot of the dipole when the charges are crowded at
the ends of the dipole: all negative charges are at one end and
all positive charges are at the other end. At this very moment,
in the proximity of the antenna there is a maximum electric field
with vectors oriented from the "positive" half of the dipole to the
"negative" half. This electric field has just reached its peak. But
in the same time there is close to zero flow of charges in the
antenna, implying that the magnetic field is close to zero.

Indeed, the magnetic field is perpendicular to the electric field;
however, it is zero exactly when the electric field is maximal.
This is called a "90 degree out of (time-)phase".

However - in theory - an accelerated point of charge creates
an EM front with an electric field and a magnetic field in
(time-)phase, i.e. they peak and die together, perpendicular
on each other. Moreover, in free space a varying electric field
generates a magnetic field in (time-)phase with the originating
electric field (without the need of any charge).

So, the problem is that the dipole generates two fields (E&M)
out of (time-)phase; whereas EM propagation in free space
implies two fields in phase. The "contradiction" can not be more
clear than this.

In order to explain this wonder, I was suggesting the following
scenario:

The dipole give us these two ortogonal fields, E1 and M1 : an electric
field and a magnetic field out of time-phase. E1 is a time varying electric
field, hence it creates its own companion - say - M2 which is a magnetic
field in time-phase! with E1. In the same time, M1 is a time-varying
magnetic field, hence it creates its own companion - say - E2 which
is an electric field in time-phase with M1.

Doing the arithmetic, we conclude that we have four fields altogether,
which represent two separate EM emissions: E1&M2 is one emission,
and E2&M1 is the other one. These two emission are obviously out
of time-phase(they inherited from their originators), i.e. when
[E1 and M2] both peak, [E2 and M1] both die. This is like saying that

the two EM radiations are 90 degrees out of time-phase.

From here on, I do not know how to continue. One way may be that these two EM radiations - as any behaving waves - sum up vectorially, and lead to a unique EM radiation with an amplitude a bit higher that the initial ones. The problem I am having with this explanation is that the wavelength is also a bit shorter - which does not sound right.

So, I am looking for a better continuation - or for a better explanation of the following : how comes that we start with two out of time-phase E and M fields and end up with an EM propagation, i.e. with E and M in time phase ?

Cordially,

Nic.

Art Unwin wrote:
"It is in this area that I view stagger tuning or coupling to be
efficient in character."

This is a struggle against nature. Like the double-tuned stagger frequency transformer, the wider the frequency separation, the less the coupling.

Another item promotes coupling in a transformer. It is placement of the coils so they share flux. An opposite phenomenon is at work for Art, as I`ve told him for the nth time. A small loop has a null in its radiation perpendicular to the plane of the loop. Art`s loop shares the plane of his dipole. The loop is suspended form the dipole and actually shares conductor.

The dipole has maximum desired radiation perpendicular to the plane containing the loop. At horizontal and low-angle directions to the earth, this is the direction of the loop`s null. No way could radiation from the loop reinforce dipole radiation.

In a yagi, the reflector is tuned lower in frequency and the director is tuned higher in frequency than the driven element. The purpose of this detuning is to get proper phasing between the elements so that director directs and the reflector reflects and not vice versa. But, in the case of the yagi, radiation of all the rods is in the same plane that they share and that contains the desired direction of signal transmission / reception.

In a dipole which shares conductor with one side of a suspended loop, the only possible loop contribution to the dipole`s radiation is straight up, or straignt down, or toward the ends of the dipole. This could help it approach an isotropic antenna more closely. The isotropic has about 2 db less gain than a dipole alone. Or, a slight gain toward the earth, the zenith, or the dipole ends might be realized, as stated before.

Best regards, Richard Harrison, KB5WZI

(rest deleted...)

Again, just to make things clear, this is fine in freespace (or good approximations of freespace), but when there are conductors and dielectrics scattered about, it can be significantly disrupted. Of course, all this is explained quite nicely by exactly the same physical understanding that Ian mentioned for the fields in the vicinity of the radiating structure. It's "only" a solution to a bunch of differential equations and boundary conditions. Things are just a lot simpler in freespace.

From a practical standpoint, it can be helpful to have an idea when it's safe to say you're in the far field and when you're in the near field. Somewhere in my files I have some articles about that (awaiting better organization so I can actually find them! ;-). I think the one I liked best was in "RF Design" magazine perhaps five years ago. The estimate takes into account not only how far from the antenna you are, but also how large the antenna is.

Cheers,
Tom

Cancellation can occur between zero waves? That's just bafflegab.
If zero waves exist, wave cancellation is impossible.

> exist.

You are again confusing cause and effect. The solution is zero in only one
direction in a transmission line and we already know that. The principle of
conservation of energy dictates that the solution cannot be zero in the
opposite direction. The two rearward-traveling wavefronts cancel each other.
Their intrinsic energy components cannot be canceled. Therefore, that intrinsic
energy changes directions and joins the forward wave. It is all explained on
the Melles-Griot web page.

>> You seem incapable of conceiving of canceling wavefronts that exist for

>>of two waves that never existed.
>
> Not my problem.

Certainly not mine. Do you really expect any rational person to accept your
assertion that wave cancellation occurs between wavefronts that never existed?
Do you also believe that marriages occur between men and women who never existed?

My solution for short pieces of coax is to use 0.2" RG-400 teflon and barrel adapters for the small coax. Soldering will not melt the coax but soldering is not required at all. The screw-down barrel holds the double braid against the PL259 body. I have had zero problems with PL259 connectors since I started this practice. For window-line fed antennas, I now use only RG-400.

Richard if you have to swipe at me then you need a mean streak
like Yuri who uses it with vigor which you do not have.
I told you that I would not bring up my antenna again but in
taking a swipe at me you have.
As you well know my antenna is a simple small dipole coupled
to a double meshed circuit one of which being an occillator
which is extremely difficult to describe.
But you can help me. Design a tuner with two variable inductors
plus a capacitor of sorts and explain that in simple language
not ignoring the effect of intercoupling between the components.
Then put all of this in a black bos which provides only one knob
to fiddle with to tune up.
I could use such an example from somebody who can walk the walk
so I could one day if ever, communicate in a more informative way
I have a slide rule that I can supply so that you can get cracking
with the project so that you can show me how things should be done
to your satisfaction.
Best regards
Art

> clear than this.

If the antenna is a traveling-wave antenna, the E-fields and H-fields will be in time phase, physically orthogonal to each other's plane and orthogonal to the direction of energy flow. Reference: "Antennas", Kraus & Marhefka, third edition, sec. 6-8. "Since the current is entirely in the 'z' direction, the magnetic field has but ONE component, H(epsilon)." The ratio of the E-field to the H-field will be the characteristic impedance of the traveling-wave antenna. Also: _Optics_, by Hecht, Section 3.2, Electromagnetic Waves.

For standing-wave antennas, like a dipole, there is MORE THAN ONE magnetic field component.

For standing-wave antennas, like a dipole, there are forward-traveling waves from the feedpoint to the ends of the antenna and reflected traveling waves reflected back from the ends. This is similar to an un-terminated transmission line. It is well known that the total net voltage and total net current can be 90 degrees out of phase in a lossless un-terminated transmission line. Approximately the same holds true for standing-wave antennas. The total net voltage is the phasor sum of the forward voltage and reflected voltage which relates to the total E-field. The total net current is the phasor sum of the forward current and reflected current which relates to the total H-field. And of course, as in a transmission line, the total voltage and total current can be almost 90 degrees out of phase at the two points equi-distant from the feedpoint and the ends. So of course, the E-field and the H-field near the antenna will possess the same phase as the total net voltage and total net current flowing in the wire at the same orthogonal plane.

Or, based on further thought, he may be talking about the forward-traveling wave plus the reflected traveling wave on a standing wave antenna. Please see my other posting. The fields generated by those two traveling-waves are superposed upon each other in the vicinity of a standing-wave wire antenna and can certainly put them out of time phase with each other.

1926. TEM planar diagrams vs. wireframe zeppelins

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-23 18:19:55 UTC
From: Loopfan <nobody@nohere.moc>
Message-ID: <flATa.130$e4.84@newsread3.news.pas.earthlink.net>
Source record: 111869

Hi everyone,

Just to point out my own ignorance: for the longest time I was trying to picture TEM waves arriving at my antenna using the typical published pictorials of planar EM fields at 90 degrees to each other.

What was really confusing was wondering why a dipole oriented to the E-plane didn't also work by trying to orient it 90 degrees out to the H-plane. This is basic theory and it presented a huge stumbling block to me.

I finally ran across a pictorial that makes it clearer - a wireframe zeppelin with the antenna in the center of it longitudinally. The wires running from each end of the zeppelin represent the electric field and the circular support frames represent the magnetic field. I suppose you could substitute all sorts of mental pictures, ie footballs, etc.

I know this is basic stuff to everyone, but for me it was a watershed moment! Now when I mentally picture throwing pool-cues and hula-hoops at my antenna, it all makes sense!

> So, there is no contradiction in my scenario so far.

Methinks the situation is a little more complicated than that. The E-field and H-field is in phase at the feedpoint of a resonant dipole. In the real world, they are never 90 degrees out of phase, but they get close to 90 degrees at the points midway between the feedpoint and the ends of the resonant dipole. The E-field and H-field are (almost) back in phase at the ends of the dipole.

The ratio of net total voltage to net total current at points along a dipole can be thought of as a spiral on a Smith Chart. It is much like a transmission line where the spacing between wires is too large for the frequency of operation and therefore leaks radiation.

Roy is correct. And if both transmit and receive antennas were
directional Yagis pointed at each other instead of regular dipoles,
the efficiency would go up.

Broadbandedness by itself is not a measure of efficiency. You
may still be very inefficient, over many octaves!

A degree of phase difference would be a boundary, just as the
-3dB cutoff point is a cut-off freq. for a filter.

Such a bold-faced lie. I have argued loud and long with Peter (and
others) that reflected traveling waves are alive and well during the
steady-state. Peter will (hopefully) jump in and verify that fact.

Why do you give in to your compulsion to lie about what I have said?
Anyone following this discussion can observe what you are tring to
do. Why can't you just stick to the technical discussion without having
to lie? Because you want to win the argument at any ethical cost?

For the record: I think that the forward and reflected waves detected
by a Bird wattmeter are really there, transporting the energy and
momentum that all EM waves possess. You are the one who claims that
those reflected waves from a mismatched load transfer no energy and
possess no momentum. That is, unless they are going to encounter a
resistor in the future in which case, they are required to predict
the future better than you can. Do you realize that your waves are
smarter than you are?

OTOH, I believe Hecht when he says: "One of the most significant
properties of the electromagnetic wave is that is transports energy
and momentum."

You seem to have chosen to dispute and attempt to discredit Hecht,
Ramo & Whinnery, the Melles-Griot web page, and HP Application Notes.
Don, good luck on dueling with windmills.

Art figured out that:
>
>Richard if you have to swipe at me then you need a mean streak
>like Yuri who uses it with vigor which you do not have.

Yuri likes propagation of radio waves and well performing antennas, he hates propagation of crap and misinformation if he stumbles on it. He doesn't care if it is Art, Freak or Tom. So far he has been more (always) right than wrong and he can spell despite of not learning English (his 7th language) at schools. Sometimes he is trying to be funny, but that is judged by the audience.

If Art tries one program (AO) and makes recommendation and "evaluation" of modeling software based on that, then he uses his "mean vigor streak" to debunk another crap. He looked at few other programs and knows that AO is still good but a bit archaic and limited. He also has seen different dimensions coming from AO optimizer and others. Who to trust? Need to get the hardware models out and correlate.

Art please use spell checker (or slide rule) because you are putting Englishpersons (xG) in bad light.

You said "Waves cannot be destroyed". I quoted Hecht saying that waves can be created and destroyed. Please tell us again that, "RF waves are not destroyed by a dummy load." When you come to understand that EM waves can be destroyed but the energy in those waves cannot be destroyed you will begin to understand EM physics.

I agree, but not really because of the noise. Because of the non
directional performance of most fairly short random wires for MW use.

Unless
> you live in the middle of the desert, and are willing to forgo modern

> Now, if you are interested in Short Wave reception, that's another matter.
> But pitfalls lurk there also.

Any kind of loop would be better than the wire. Doesn't really have to
be shielded, although that might reduce local noise a bit. I've tried
both, and could tell little difference. I use a 12 turn-16 inch loop
for MW, and local noise is very little problem at all. I have wire
antennas of various lengths and none are as good as the loop for MW.
The wires are too short to be directional on MW, and you get 4
stations on each freq. With the loop, you can null out noise or
unwanted stations. Adding a random wire is fairly useless for most
decent MW radios with a ferrite antenna inside. The s/n ratio will
rarely increase unless the ferrite antenna is really micky mouse. In
some case, the s/n ratio may decrease being the ferrite antenna is
directional and the random wire is not. MK

Nic. Santean wrote:

> We are talking about half wavelength dipole antennas, right ?

Yes. A 1/2WL dipole can be thought of as a very leaky transmission line. It has standing waves that leak radiation into the ï¿½ther. :-) May I suggest trying to understand traveling-wave antennas before getting into standing-wave dipoles? Consider a terminated V-beam or terminated Rhombic to eliminate the confusion associated with reflected waves. But don't feel bad about confusion associated with reflected waves. Some of the r.r.a.a gurus don't understand reflected waves and the energy plus momentum involved in their very existence. So many sacred cows - so little time. :-)

These waves never propagate. You can call them waves if you like, but
they are only mathematical constructs. Cancellation precludes their
existance.

> >>Cancellation requires at least two waves.
> >
> > :-) Cancellation requires zero waves You can't have it both ways..
>
> Cancellation can occur between zero waves?

No. Zero waves occur because of cancellation.

> If zero waves exist, wave cancellation is impossible.

The waves which impinge upon the boundary certainly exist. But V3 and
V4 do not exist because their existance is prevented.

> >>Maxwell's equations contain partial differentials
> >>for dx, dy, dz, and dt.

> > superposed functions of equal amplitude an opposite phase, the solution is
> > zero. You can write the functions for the two waves and prove they cannot
> > exist.

> You are again confusing cause and effect.

To you that is a truth. But it certainly is not a fact. And you
certainly can't dispute that for any set of finite values of those
variables for two superposed functions of equal amplitude an opposite
phase, the solution is
zero. That means, the waves do not exist. They don't disappear. They
never appeared.

> The solution is zero in only one
> direction in a transmission line and we already know that.

The functions are only in one direction! Are you claiming that a wave
in a transmission line can move in more than one direction at a time?

> The principle of
> conservation of energy dictates that the solution cannot be zero in the
> opposite direction.

:-) Actually, it's not quite that specific. The conservation of energy
principle says that energy in equals energy out minus losses. In the
case of optics we say that transmitted energy equals incident energy
minus reflected energy. Wave cancellation prevents energy from being
reflected, and thus transmitted energy equals incident energy. That's
what the conservation of energy principle says about this. You're
making up the rest.

> The two rearward-traveling wavefronts cancel each other.
> Their intrinsic energy components cannot be canceled.

There is no intrinsic energy in waves that never propagate.

> Therefore, that intrinsic
> energy changes directions and joins the forward wave.

Once you get an idear in ur head, there's no shiftin' it.

> It is all explained on
> the Melles-Griot web page.

If you think that Melles-Griot "explains it all" you're seriously
deluding yourself. Melles-Griot would even think of making such a
claim. They certainly havenn't supported your claims about what they're
saying - have they.

> >> You seem incapable of conceiving of canceling wavefronts that exist for
> >> only a dt of time.
> >
> > Since the functions cancel during that dt of time as well as any other
> > length of time, you're right.

> Your inability to conceptualize is your problem, not mine.

So you're claiming that the functions don't cancel during time dt? I
think that's more indicative of an inability on your part with respect
to mathematics.

> Certainly not mine. Do you really expect any rational person to accept your assertion
that wave cancellation occurs between wavefronts that never existed?

Do you really expect anyone to believe that waves can both exist and not
exist at the same time?

> Do you also believe that marriages occur between men and women who never existed?

Do you believe that radio waves emerge from your radio when they are prevented from emerging from it?

Try "cease to exist". Here's what you said. Read it and weep.

> Waves cannot just "cease to exist" for the very same reason that
> energy cannot cease to exist.

"Ceasing to exist" and "being destroyed" are identical events. Waves
that are destroyed cease to exist. Waves that cease to exist must,
of necessity, be destroyed. So where did you learn your ethics? At
the rattlesnake farm?

NO IT IS NOT WHAT CAME WITH THE RADIO!

What came with the wire is a T, not a folded
dipole. No I have no idea of what I am talking
about. I did not work there for 6 years. You
appear, on the surface, the customer who would not
listen, to whom I happily sold the useless
amplified antennas for $30 to $50.

Dresser Industries I know--good customer.
SCADA, I have worked with for 40+ years, although we usually supplied our own RF/microwave interconnectivity. Used to be a good use for the 900 meg band before all this cell nonsense. I guess that applies to 2 GHz for the past ten years also.
Low frequency carrier current is familiar to me, the office next door to mine in Lynchburg in 1960 is where GE designed their carrier current signalling equipment.

So, where are these "repeaters" you blithely cited the existence of? Power line carrier is regularly discussed in Transmission and Distribution News as well as other electric utility magazines, and I do not recall seeing any reference to any equipment outside substations associated with carrier current signaling. I submit that the isolation inductors alone qualify the location as a substation anyway, nevermind the ceramic posts they call coupling capacitors.

Jim Kelley wrote:
> These waves never propagate.

Of course not and I NEVER said they did. That's just another strawman of yours. The wavefronts originate in and are canceled in a 'dt' of time. What is it about calculus that you do not understand?

>>Cancellation can occur between zero waves?
>
> No. Zero waves occur because of cancellation.

Bafflegab!!! The energy in the waves CANNOT be destroyed. Zero waves occur in one direction. The energy in the canceled waves flows in the opposite direction. So says every physics book that I own. Sorry about that.

You have said:
> Waves cannot just "cease to exist" for
> the very same reason that energy cannot cease to exist.

This is the biggest bunch of BS that you have ever uttered! On what planet do you live that photons must be conserved?

> The waves which impinge upon the boundary certainly exist. But V3 and
> V4 do not exist because their existance is prevented.

Without their existence, wave cancellation is impossible. Yet you have agreed that wave cancellation exists. Which is it? Does wave cancellation exist? If yes, then V3 and V4 exist. If no, then come up with an explanation that doesn't involve wave cancellation. (Your spelling of "existance" sic, is driving me crazy. Please correct it.)

> To you that is a truth. But it certainly is not a fact. And you
> certainly can't dispute that for any set of finite values of those
> variables for two superposed functions of equal amplitude an opposite
> phase, the solution is > zero.

What you are missing is that your solution is only for one direction. The other direction contains the reflected energy as proven by a Bird directional wattmeter. Aren't you capable of conceptual thoughts involving the two directions in a one-dimensional environment? My dog is almost capable of that.

> Are you claiming that a wave
> in a transmission line can move in more than one direction at a time?

No, I am claiming that the energy in waves can reverse direction in a 'dt' of time. Do you disagree?

> :-) Actually, it's not quite that specific. The conservation of energy
> principle says that energy in equals energy out minus losses.

Bafflegab! The conservation of energy principle says the energy in an
electron can be tracked to an electron plus photon and back. Good Grief!
Are you really teaching physics students? If so, I feel sorry for them.
Does your boss know that your are teaching bafflegab?

> There is no intrinsic energy in waves that never propagate.

Optics, by Hecht says that all EM waves propagate and contain
energy and momentum. Sorry about that.

> Once you get an idear in ur head, there's no shiftin' it.

I really admire your technical assertions, I really do. When
are you going to make one?

>>Your inability to conceptualize is your problem, not mine.
>
> So you're claiming that the functions don't cancel during time dt?

Of course, they cancel during time dt. Why do you feel the compulsion
to erect those more-than-obvious strawmen? That's usually the diversion
of someone who is desperate after painting himself into a corner. Why
do you feel the need for diversions? Why can't you just discuss the
technical aspects?

> Do you really expect anyone to believe that waves can both exist and not
> exist at the same time?

No, that's just one of your strawmen. I expect some people to accept the fact
of physics that a wave can be destroyed by wave cancellation as described in
Optics, by Hecht and on the Melles-Griot web page.

1951. Re: 30 meter add-on for HF2-V idea

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-23 21:39:15 UTC
From: John <my-callsign@qsl.net>
Message-ID: <9gDTa.524$c17.448226@newsfep1-win.server.ntli.net>
Source record: 111917

I used to use a 40mtr quarter wave wire vertical and a 30 mtr quarter wave wire vertical in parallel up a 10mtr fibre-glass pole and it worked fine, though they were separated by about 5 inches. Coincidentally I now have a HF2V with the 30m add-on kit but I'm sure you could run a parallel 30mtr quarter wave instead of the add-on kit. The Butternut 20 mtr add-on kit for the HF2V is a piece of wire, a quater wavelength long, fed in parallel with the main antenna.

The same 'dt' of time. The waves would cancel for any t and any x.
What a ridiculous argument to be having.

> >>Cancellation can occur between zero waves?
> >
> > No. Zero waves occur because of cancellation.
>
> The energy in the waves CANNOT be destroyed.

Zero waves=zero energy.

> Zero waves
> occur in one direction.

That's what I just got done saying and you called it "bafflegab" or some
such thing.

> The energy in the canceled waves flows in the
> opposite direction.

The energy definitely flows in the opposite direction - from source to
load. You keep claiming it's flowing toward the source. That's what the
argument is about. Remember?

> > The waves which impinge upon the boundary certainly exist. But V3 and
> > V4 do not exist because their existance is prevented.

> Without their existence, wave cancellation is impossible.

They don't exist, and there's nothing besides cancellation to explain
their absence.

> Yet you have
> agreed that wave cancellation exists. Which is it? Does wave cancellation
> exist? If yes, then V3 and V4 exist.

Wave cancellation exists, and as a result V3 and V4 do not. Very
simple.

(Your spelling of "existance" sic, is
> driving me crazy. Please correct it.)

Short drive, methinks.

> What you are missing is that your solution is only for one direction.

There is only one solution to that equation - and it is for one direction only. The forward moving energy is expressed by a different equation, obviously with a different solution.

> The other direction contains the reflected energy as proven by a Bird
> directional wattmeter.

Yes, the wattmeter says 133.33 in one direction and 33.33 in the other direction.

> > Are you claiming that a wave
> > in a transmission line can move in more than one direction at a time?

> No, I am claiming that the energy in waves can reverse direction in
> a 'dt' of time. Do you disagree?

A wave going in a different direction is kind of a different wave, to my way of thinking. Maybe you could ask your dog what he thinks about that, and let us know.

> > The conservation of energy
> > principle says that energy in equals energy out minus losses.

> Bafflegab!

So are you saying that energy is not conserved when energy in equals energy out, minus losses? Or are you saying that energy is conserved when energy in does not equal energy out, minus losses?

> Does your boss know that your are teaching bafflegab?

Actually, he says that I'm conversing with a nutcase.

I wrote to the address given by Roy in his posting on this thread.
Return contact was made by E mail and the programs were sent by
computor.
There were interchanges after receipt because I am computor
illiterate but Brian hung in there with me until it was off and
running.
By the way AO also came with AO pro and there was not any of those
irritating keys that were designed to prevent theft which then became
a problem for users. The manual that comes with the programs are
extensive
and leave nothing to question. If I was able to follow them then most
people on this newsgroup will testify that they then must be very
good.
I would point out again that I only have experience with AO and by no
means can be seen as being an expert so comments made by others should
also be heeded.
Best regards
Art

I've never soldered the outer braid either.

Folding it back and tightening down the connector
over it has worked well for me for over 20 years.

This even works well when using reducers for
58, 58 & 8X. Fold the braid back over the reducer,
tighten, solder the center pin, and your done.

Cec sed -
> What is it about calculus that you do not understand?
>
==========
Cec, and to whom it may concern,

Probably most of it.

Here in Euro-side an amateur radio ticket can be obtained without ever having heard of it. And what with present educational standards that's nearly all of us.

The trouble with Guru's displaying their knowledge on this newsgroup is failure to appreciate the technical standing of their 'pupils'. Yet as often as not the manner in which questions are asked are a dead giveaway. For a reply to be of value it is necessary for the Guru to 'tune in' to the recipient, ie., become resonant in same sort of language.

Too seldom is any thought given to it. As a result I would guess many questioners become so confused or overloaded with haggling between the 'experts' they don't bother reading to the end of the thread, possibly to consider packing up the hobby. It is impossible for a novice in a particular subject to distinguish wheat from chaff, or to choose between one old-wive's tale and another. Confusion reigns!

So KISS ! In plain unabbreviated English.

To refer to Terman et al to somebody who has probably never heard of any of 'em is no better than uninvited spam and indicates a lack of self confidence.

But who am I to lay down the Law? Tonight's plonk is Claret. Vive La France! Hic!

According to Calculus, not ridiculous at all. Many things happen in a delta-t of time. Some things only happen when delta-t approaches zero. I suggest you review Calculus. At the moment, you are clueless.

> Zero waves=zero energy.

This is commonly known as "assuming the proof". Sorry, but first you have to prove that there are zero waves which is obviously impossible.

>>The energy in the canceled waves flows in the
>>opposite direction.
>
> The energy definitely flows in the opposite direction ...

So what is your objection? For reflected energy from a mismatched load to flow in the opposite direction it must somehow be re-reflected. I have presented a re-reflection method. You haven't.

>>Without their existence, wave cancellation is impossible.
>
> They don't exist, and there's nothing besides cancellation to explain
> their absence.

Another clear confusion of cause and effect. Their absence cannot cause their absence. Your assertions are ridiculous and I suspect you would be fired if your boss knew about it.

> Actually, he says that I'm conversing with a nutcase.

I've heard of back-scratching college departments like that. Sooner or later they come tumbling down just like the Catholic Church in Boston.

> Wave cancellation exists, and as a result V3 and V4 do not. Very
> simple.

You are extremely confused. Wave cancellation cannot exist without the canceled waves which are V3 and V4. If V3 and V4 don't exist, then wave cancellation is impossible. If wave cancellation exists, then V3 and V4 exist if only for a 'dt' of time. How you can deny the rules of Calculus is beyond belief.

> A wave going in a different direction is kind of a different wave, to my
> way of thinking.

Yes, it is a different wave, i.e. not the same wave as V3 and V4. It is
a constructive interference energy wave defined in _Optics_ as 2*Sqrt(I1*I2).

>>> Zero waves occur because of cancellation.

>>Bafflegab!

> So are you saying that energy is not conserved when energy in equals
> energy out, minus losses? Or are you saying that energy is conserved
> when energy in does not equal energy out, minus losses?

No, I'm saying that your statement above is bafflegab. Zero waves IN
ONE DIRECTION occur because of cancellation. That causes a coherent energy
wave in the opposite direction which can be viewed as an energy reflection.
It does NOT cause zero waves in both directions as you imply.

That's exactly what I try to do, Reg. But everyone keeps asking me to
prove my concepts using Maxwell's equations, as if that was possible
on an ASCII newsgroup. My attitude is: If they are incapable of
arguing concepts, then they probably don't know what they are talking
about anyway. When I ask for a conceptual thumbnail sketch and am refused,
that's exactly what I assume. Even Einstein was capable of presenting his
relativity concepts in a language that most technical people could understand.

Get a 175 watt Weller, then you'll be able to solder it through the
four holes in just a few seconds, like it's designed for.

Got a Wirebook III from The Wireman? RG-400 is a 0.2" 50 ohm teflon coax
with a 1900V RF tolerance. It's all I ever use anymore inside the hamshack.
Great for four foot cables and baluns.

In a word, NO. Not worth the paper they aren't written on. Next week, I am going to be doing some library research at a technical library, and I am going to scan through the issues of IRE Transactions on Power Equipment, or whatever the name was pre-IEEE, from 1950 to 1965 or so, and I'll get back to you. I already know the answer, and I think so do you. For your part, why don't you start a movement within IEEE to put their pre-1990 publications in their digital database?

I assume 400 KHz Power Line Carrier is hardly anything like BPL which,
I assume, is a lot broader banded than that. Power companies use Power
Line Carrier equipment to control sub-stations from a central location.
They don't generally use it between the sub-station and residences so it
is usually not a problem for hams. But I have heard of power companies
using Power Line Carrier systems to read their meters under computer
control. Do you have any other specific questions? I'll try to dust off
my failing memory and answer them.

Bill,
It really is better if a connector is installed as it's designed to be installed. It may not be the easiest way of doing it, but it's almost always the best way.
Having said that, I've found that using a propane torch is the easiest way I've found to put on a PL-259. Takes a little practice (and don't use MAP gas!), but not a problem even in high winds. It helps to pre-tin any adaptors, etc.

Hi Yuri,
W4RNL has a very nice tech note on his site relating this shortening effect with respect to the thickness of the dielectric and its dielectric constant. I used this on my latest 20M Moxon and it came out right on the money.

Frank Jones (W6AJF) - Google is your friend

I was thinking about the coax collinear but I never could make them work.
I did find a reference about the velocity factor if the center being different from the sheild. This messed up the phase relationship.

It appear the original antenna this was copied from had the whole antenna potted in wax to fix that. Maybe build one out of the air dielectric coax I have in the garage?

I guess I'll just drag out the formulas for parallel line and stubs. Whip something out of copper pipe and the wife poly cutting board she don't use.

So, how does one mount a 10' copper pipe antenna to a mast? Beside on a dare....

Mike

You could also try LMR240. Loss at 50MHz is only 0.1db/100 more than 213, but it is 0.24 diameter. Works with RG6/59 reducer. About $45/100 feeet. I have some connectors with shield soldered, some not. There is also a LMR240 Flex, which is really nice for patch cords, but costs a little more. I have put a KW through both of them at HF.

Myself, I think using a high wattage gun is one of the most important
parts. It's hard to get them hot enough with a small 30-50?? watt gun.
To properly solder, you have to get the shell itself hot enough to
melt the solder. Otherwise, you have a cold joint. But, on the other
hand, you also don't want to sit there for 8 min trying to get it hot
enough, when in the meantime the coax melts into a blob. So you have
to get in and out fast. A hot gun is the only way. I've been using a
150 w for quite a few years and it seems big enough unless you are
outside in the wind. I do a lot of brazing with oxi-acetylene torches,
and follow the same rule. I use a lot of heat and have smooth clean
welds that also lets the solder flow back inside the joints by
capillary action. I rarely have to go back and redo welds. Maybe 1 out
of 80. And those are usually ones I have bad access to the backsides
of the pipe. The guys the don't use enough heat have rough, crappy
looking welds. Using too low a heat soldering ends up with the same
type of joints. A hot enough gun will let you solder even the cheapy
"hard to solder" connectors..:) MK

Dunno, I think they still need to give Bin Doo-Doo a touch up. He
seems to still be slithering around somewhere. I consider him the
worst of the lot, considering his recent actions, and everyone seems
to have forgotten about his slimy carcass. Something occurred to me
recently. Bin Doo-Doo probably thought when he did the 9-11 thing that
we would all wilt over, whine and moan for a while, and all would
continue to be biz as usual in his part of the world. Probably
considered Sodamn Insane one of his close partners in crime. Probably
thought they would be out water skiiing about this time, celebrating
their crushing defeat of the dreaded yankee redneck infidel bastards.
But now his group is half toast after being given a healthy round of
air to ground enemas, and same for ole Sodamn. His days are numbered.
Bin Doo-Doo brought the wrath of Bush on the whole group of terrorist
deathmonglers and dicktaters. I bet Sodamn curses Bin Doo-Doo's name
when he hovers in his fortified double wide to attempt fitfull sleep
at night. Who wants to be next? Come on boys, lets spin the wheel and
get this show on the road before we are all broke. Making all those
high $$$$ missiles will boost the economy in certain parts of the
country. MK

W7TI wrote:
>IMO, a poor design to begin with.

There is the alternative of the pressure-sleeve PL-259, which fits regular RG213 or RG58, and you assemble it by screwing down a nut. Only the centre conductor requires soldering.

"This is not your father's MIL cable clamp" as used on so many BNCs and Ns of US origin, which tears off the braid and pulls out easily. This one works - the whole cable will tear apart before it pulls out the rear of the plug. Pressure-sleeve BNCs and Ns are so much better, I won't ever buy the old MIL type any more.

More recently, PL-259s and cable jacks have become available with the pressure-sleeve clamp too, mainly through the Multicomp brand sold by Farnell in Britain. Try www.farnell.com/uk and search for order codes 724804, 724816 as examples. The product line includes plugs and cable jacks for RG213 and for RG58 - that's two separate sizes (no adaptor).

These connectors are more expensive, but they are the only ones that avoid the problems of heavy-duty soldering outdoors. For that situation they can be an absolute godsend.

(Well, there's also crimp, but crimp is one of those techniques that's useless unless it's done perfectly. The price of the correct tool to make a full hex crimp around RG213 will buy a lot of pressure-sleeve connectors. Also, the pressure-sleeve clamp is waterproof in its own right, which the crimp is not.)

Last time I posted this information, about two years ago, there was a lot of interest from the USA, so here's what I know.

Availability in the USA used to be poor... and may still be. The pressure sleeve clamp was invented by the British company Greenpar AFAIK, but was also licensed to G-E who used to make a PL-259 and may still do so - so G-E is one place to look.

Otherwise you have to follow the company takeover trail, to see where the technology went. Greenpar was bought by M/A-com and the idea seemed to disappear; then the M/A-com connector line was bought in turn by AMP and by Tyco.

The Greenpar name has recently resurfaced as a Tyco brand, and quite possibly the connectors have too. Farnell now stock a "Tyco Greenpar" PL-259 which is probably pressure-sleeve, and obviously will be available in the USA (but even more expensive than the Multicomp connector). Another possible lead in the USA is Newark, which is owned

by Farnell and is now beginning to stock some Multicomp parts.

I use an 80 watt Weller iron. It holds far more
heat (not temperature) than my 250 watt soldering
gun. Because of the heat capacity of the iron,
the holes solder very quickly and easily. It is not
necessary to pre-tin the braid.

A 100 watt iron might be a little better, but they
are harder to find. Some hardware stores carry
the 80w Weller.

No, but he will be if he keeps arguing with you. Most of
the rest of us value our mental health too much to argue an
infinite thread with an obsessed Texan.

Cec, from where do you get all your energy?

Is it from fire water you have now stopped trading for buffalo hides from
the injuns?

Reg

Art Unwin wrote:
"As far as I am concerned you do not have the faintest idea what my antenna consists of ...or,,you don`t know what you are talking about."

How does Art`s antenna differ from Fig 10(A) on page 26-9 of the 19th edition of the ARRL Antenna Book?. In that figure, the input of the "T" is inductive until the series capacitance brings it into resonance.

The tuning section of Fig 10(A) forms a small loop. See Fig 4 on page 5-3 of the same Antenna Book for the small loop radiation pattern. Also, see Fig 12 on page 2-8 for the dipole radiation pattern. Note that lobes are perpendicular to the wire and plane of the dipole, and perpendicular to the axis of the small loop. There are nulls perpendicular to the wire and plane of the loop.

The loop`s null can`t help the dipole`s lobe. It can`t hurt it either, other than by radiating some energy that might otherwise have gone into the dipole. As the loop is small (< 0.1 lambda is one definition), its contribution to radiation may be small. As the loop size grows, so will its radiation, and its null will decline.

How does Art`s antenna differ from a T-matched dipole?

Best regards, Richard Harrison, KB5WZI

I've used it here with no problems. Outside I use N connectors for
nearly all connections.

>While struggling as usual to attach some PL-259s to some Belden 9913F,
>it occurred to me that the four little holes for soldering the braid

For the purist connecting there helps keep the impedance correct, BUT
as you took the braid inside I would expect about the same.

Contrary to what some have said, I've not been able to see any bump
using a Time Domain Reflectometer (TDR) with that approach.

>you have a good connection.

When it comes to weather proofing, PL259s are not weather proof. You
just make it a little easier for the water to get in.

I use "flooded" heat shrink tube over the connector and out onto the
coax by about an inch and a half. I purchase it in 4' lengths at the
local electrical supply house. The flooding material is pretty much
the same stuff used in hot glue guns.

You have to remember to start shrinking the tube in the middle and
work out to the ends

>

>
>Another advantage is you can trim the braid much farther back from where

Here you don't want to trim it back much father than the normal
installation.

I cut and trim to length, then tin the braid. If need be (and it
usually is) I file down the solder so the braid easily fits all the
way in to the proper position and I don't have to worry about
"whiskers".

>you strip the center conductor. This helps reduce the chances of a

>else it's just holding on by the four holes and the center conductor.

Yes, Yes, and no.
Yes, the solder will eventually fatigue.
Yes the connection should be supported, or strain relieved.
No, those little solder spots are an electrical connection, not to
support the cable.

Most of what little strength a pl259 has, comes from the jacket being
screwed down into the connector.

My assessment as one of the "less washed" is that I can kind of
understand some of what is being argued.

But too much pouncing on minutaia, too much of what sounds like the
antagonists saying the same thing in a different way, and too much
personal junk all over the place, and it ends up doing everyone no good
at all, especially the antagonists. But of course, it doesn't really
matter what I think. I suspect that despite some aggravation and
digestive tract angst, they are enjoying it.

In the end, it is just a Warholesqe repetitive, stretched out artwork.

> So KISS ! In plain unabbreviated English.

Or (ironically enough -- Occam's Razor!!-- 8^)

1989. SGC Tuners with Dipoles ?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-24 20:49:49 UTC

Hi,

Does anyone use an SGC tuner (coupler) with a dipole, and if so, how do you have it set up. I was thinking of the tuner at the base of the tree, 60' of ladder line up the tree, then split into the dipole. I know most use these tuners for longwires or with whips, but I am looking for info and experiences on dipole configurations.

Thanks in advance.

MW

Hi OM,

You might want to put ferrite chokes on both the coax feed into the
SGC and around its control lines as well. There is a definite
possibility of common mode on the line (hence the chokes on the lines
back to your shack) and some blurring of the usual directionality.

Yup, just takes a little time, they can run they can hide but one day they will get tired
of running and they will be TU.

Can't figure out why both sons were together on the run ?

Kind of dumb unless they knew their days were numbered.

Never forget our troops, past and present and our Sept. 11 victims.

> You're arguing with me about it right now in another thread! :-)

The statement, "Reflected traveling waves disappear in the steady state",
means to me that the set of reflected traveling waves is null in the
steady-state - which is a statement that I never made.

In a system with a mismatched load, reflected traveling waves always
exist and I have NEVER said otherwise.

Semantic tricks and traps never prove anything. They just obfuscate.

Cecil, W5DXP wrote:
"Trouble is, Terman didn`t say anything about what happens to the intrinsic energy that existed in the waves before they were cancelled."

It is in there. The waves go away.

Terman said:
"---there is no reflected wave on the generator side of the stub (the reflected wave produced by the shunting impedance of the shunt line is equal in magnitude and opposite in phase to the reflected wave existing on the line as a result of the reflection from the load impedance ZL)---."

It is clear that the energy reflected from the load side of the junction is neutralized by a deliberately reflected equal and opposite energy from a stub, strategically sized and placed. Terman says the reflected energies cancel. Terman provides formulas and a table for this execution. Repeating for emphasis and illustration, Terman says no reflection exists on the generator side of the junction. The load takes power accorging to ZL. It doesn`t avccept any extra energy.

Equal and opposite reflected energies at the junction are a short. The energy can`t disappear. It does not go back toward the load. Half has already been there. The other half has alredy been reflected by Zstub. Only one route is left to the reflected energy, but Terman says there`s no reflection on the generator side of the junction. Your Bird wattmeter won`t see any reflected power. What this says is that the stub produces an impedance match and the incident energy becomes the same as the generator output and load energies.

Best regards, Richard Harrison, KB5WZI

Probably because they didn't trust each other in transporting $50 mil, or waiting for some OK to move outside YI. Looks like they trusted their host, who was apparently Saddams cousin, but was locked up before. What a way to get even! If Sodumb is alive or dead, they probably hinted something to their host or was picked up by surveilance gadgets. Maybe daddy is not far away. Lets hope, so I can change to "noBin".

For anyone that wants to save their radio waves from an RF intrusion
of the greedy type, read on.

This is much more important then the CW issue.
This is a real problem in the making for ALL RADIO USERS!!!

Write your congressperson, write the chairman of the FCC, write letters
to the editors. Speak loudly. Speak often against BPL. Do not take this
issue lightly. Do not assume someone else will do it for you.

Our radio waves are in JEOPARDY!!!

> digestive tract angst, they are enjoying it.

==========

Mike, you are undoubtedly correct. If you ask a man why he keeps banging his head with a hammer he will reply that he likes the feeling when he stops.

To put it in engineering terms, all living and dead materials take the line of least resistance as perceived by their senses at the present instant of time. The result is an unending drunken "Monte-Carlo" walk.

At MY present instant in time I am about to pour another glass of delicate Chinese "Great Wall" white wine. If the disused coal mine under this house, a consequence of the industrial revolution, doesn't fall in I may yet survive to enjoy it.

There are an infinite number of ways our 'pleasure centers' make good use of amateur radio. Between them Cecil and Co. know them all !

Hi Joe,

Write the Republican Guard and ask them why:

1. They refuse to extend $6000 in death benefits to GI's ("An
unnecessary diversion of resources, Bushï¿½s budget people sniffed.");
2. They want to roll back recent modest increases in monthly
imminent-danger pay (from $225 to $150);
3. They want to cut family-separation allowance (from $250 to $100)
for troops getting shot at in combat zones;
4. They can't seem to find time to make progress on minor tax
provisions that would be a boon to military homeowners;
5. They don't care about easing residency rules for service members
to qualify for capital-gains exemptions when selling a home;
6. They also proposed capping raises for E-1s, E-2s and O-1s at 2
percent;
7. $9.2 billion military construction request for 2004, which was set
a full $1.5 billion below this year's budget;

As the Army Times has noted about the Bush White House's support of
the troops:
"President Bush, the commander in chief himself, rode a Navy jet
to the aircraft carrier Lincoln to bask in the reflective glow of some
of the brave Americans who helped oust Saddam Hussein.
"Money talks -- and we all know what walks."

That makes no sense at all... What is 'key your elements' ?

Do you mean to set your carrier frequency to the carrier frequencies of the
interfering BPL signal? If so say so.

"elements" as in the individual di's and dah's the make up each character.

I've been looking at the .gif from Texas Star, and have already learned
to copy a few characters. The first one I learned is "3". All the calls
here have it. Also "k" and a few more in my call.

dah-di-dah dah-dah-di-dah?

I figured with my musical background, it would be easy. I just don't like
you guys trying to force feed it to us. It won't look good on your shoes. <:

Cecil, W5DXP wrote:
"What does Terman say in Sec. 4-11?"

I gave a verbatim response from 4-11 at 11:03am on Jul. 17, 2003.

I`ll add the footnote from page 109:
"Another way of expressing this situation is to say that the stub position and length are so selected that the input impedance of the line (l1) shunted by the input impedance of the stub-line (a) will equal the characteristic impedance Zo." (l1 is the length of line between the stub and ZL. Fig. 4-17 provides position and length of the stub vs. SWR.

The conclusion is that a match is achieved so there is no reflection on the transmission line. The match has eliminated the reflection which was there during the transistion period, but no longer appears there during the steady state. Your Bird wattmeter will show a forward power but no reflected power because the load with its stub provides a match to the transmission line.

Best regards, Richard Harrison, KB5WZI

> outside in the wind.
[snip]

Agreed!

If you are just getting a new iron for coax connector work, go for a big
fat 200 Watt job. It not only gets the temperature correct for perfect
joints,
but because it is big it can supply a lot of heat quickly without
temperature
drop and that's the secret to great PL259 connector soldering jobs.

The 200 Watts ensures that you can do connectors quickly and
with quality even out doors on field day with the wind blowing.

Dont' fuss, don't worry...

Just do it right!

A Big Fat 200 Watt iron makes soldering coax to PL259's dead simple!

Personally, I've had the best luck with a 100-200 watt iron for soldering the shell. The iron, assuming it has a heavy tip, has enough heat capacity to do the job quickly. With a soldering gun, even a 150 or 200 watt gun, the tip just doesn't have enough thermal capacity to do the job as quickly. But, whatever works is fine.

Cecil, W5DXP wrote:
"Would you publish an example?"

I am error prone as anyone reading many of my postings may attest. The 1955 edition of Terman`s "Electronic and Radio Engineering" is the culmination of about 25 or more years of Terman`s work which was checked, rechecked, then checked again. It`s stood the test of time ever since its publication too. In Sect. 4-11 are answers to questions of impedance matching to transmission lines.

I think Terman should be consulted straight away for a simple logical cause of no reflections. It is called impedance matching. The match does away with reflections.

> dielectric coax I have in the garage?

The coaxial collinear works fine if done properly. You do NOT have to put the thing in wax to make it work. I wrote a paper on how to do it properly, but the key is to use sections 1/2 wave long taking into account the VF of the line, so that the voltage across each gap between adjacent sections is the same, and all in phase. The feedpoint impedance will be somewhat reactive since the elements are shorter than a half-wave, and the impedance will depend on the number of sections (since they are all fed in parallel, and there's a mutual impedance to consider), but you just provide the proper matching network for that, and you provide proper decoupling from the feedline. It's easy to put together an eznec or similar model to show that it works fine in air, no wax needed. And it works in practice as well as in theory.

The old ARRL writeup on the coax collinear was rather messed up, and my lack of success building them a couple times led me to think it through much more carefully and learn HOW to do it.

Cheers,
Tom

Howdy Arie and fans,

Dale W4OP, found the link to W4RNL dissertation on modeling insulated wires at
http://www.cebik.com/amod/amod50.html
which shows how NEC4 engine considers insulated wires.

Among other things on the page I have found that I was not of the rocker after all, when I was talking about the "electrical length" of conductors used in the antenna. I was "grounded" by some NG purists that IEEE dictionary or reference books do not use or mention that term. To me it made perfect sense, just as with coax and feedlines. If we are looking for the resonant or corresponding electrical length of the "wire" we know that we can end up with different physical length for the same frequency between the thick tubing and thin wire. This is important especially when dealing with parasitic arrays, where resonant or electrical length is important and physical length can be then derived from it to maintain proper function of the array.

Here is what W4RNL 'splains also:
<<For a long time, antenna builders have been aware that insulated antenna element wire has a velocity factor. The electrical length of an insulated wire will be longer than the physical length to a degree that depends upon the type and thickness of insulation. Expressed from a different perspective, a resonant dipole for some given frequency and wire diameter will be shorter if the wire is insulated than it will be if the wire is bare. How much shorter the insulated dipole will be depends on the insulation. >>

So feel free to use the term, no need for royalties.
I feel not SoDumb :-)

> away with reflections.

Not directed at Richard, but I've seen the following logic used
often with EM waves.

What causes the match? The cancellation of reflections.

What causes the cancellation of reflections? The match.

Does anyone else detect the circular logic problem in the above?

Another one:

'rho' is zero because there are no reflections.

There are no reflections because 'rho' is zero.

Richard,
When it comes to looking up books for quotations
you do a good enough job to be a librarian, but I am unaware
of any instance where a librarian was promoted to the engineering
section on a project basis. Each of the instances that you quote
are simple and direct..... as long as particular conditions are
followed.
When you strayed from your books to combine two situations it would
be wise for you to analyse the new situation to check for changes
in conditions. Unfortuately for you this will not be neatly laid out
in your books
In the case of a so called magnetic loop there are many conditions
to be met to ensure a figure 8 radiation pattern, with or without
deep nulls.
Thus just any old loop in any sort of conditions such as being
coupled to another object or not uniform in cross section e.t.c.
is not the same as the conditions that you referenced in the
handbook thus statements that regurgitate may well not now apply.
It is a pity that you do not have a interest in computor programs
or an interest in using one because if you did you could add to
your experience without the need of buying another book.

Thanks John. I think I will give it a try next week and post the
results. I reckon I should space the 30 meter quarter wave wire at
least 5 inches from the HF2V. I will probably get some sort of
non-conductive stand off and clamp it to the aluminum tubing. I have
a beam for the higher bands so I don't really need 20 meters.

Mark,
One thing that came out from the 9/11 episode is that world dominance
is shown once again to be transitory. Just a few people dealt us a
heavier blow than we have ever had before. Turned a healthy bank
account to our worst deficit ever and placed us in a position that we
now do not have enough troops
to do the governments bidding. When we decided to trash the Koran and
supply arms to those who wish to push its devotees aside in search of
land we entered a terrible path. A war against freedom of religeon
which energises those people to action against which the largest army
ever assembled will never be able to subdue. Rather than say 'bring
them on' would it not be better to understand what brings millions of
people together against the most dominant government
on earth at the present time and why they are willing to lay down
their lives for what they believe in.
If we persist in hanging on to the western ideas of punishment i.e.
imprisonment or death then we all have a rough row to hoe when our
opponents see death as redemption and who already live amoungst us.

Now as I was saying about antennas i.e . conjugate matches.....

2029. SWL tuning an MFJ loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-25 06:10:36 UTC
From: wasatch@jps.net
Message-ID: <3a31dd1d.0307242210.3cdbdd1a@posting.google.com>
Source record: 111774

Please consider this a newbie question. Am an SWL, not a HAM, and am considering an MFJ loop as the primary indoor SWL antenna, along with an active antenna as a less potent secondary, the two connected via an antenna switch.

So lets say I read in a schedule that a certain frequency in the 49 meter band right now should have an interesting broadcast station on the air, so I set my receiver digital readout to that freq, then what's the procedure to tune the loop to that same exact frequency, having no transmiter?

Thanks for any help!

Hi OM,

What you need is a device known as a "noise bridge." This takes the place of a transmitter by putting pink noise onto the line into the receiver (the antenna input) and uses the tuning of the antenna (more often the usual antenna tuner, but for you the MFJ loop) to adjust the receiver for maximum noise signal coming from the device. Actually, the unit is not a bridge at all, but is the source within a configuration using your receiver to define a bridge relationship within the system.

This device is a wideband RF generator (a "pink noise" source, called pink because it is not necessarily DC to daylight in bandwidth, merely wide banded for SW or HF - others may call this "white noise" but terminology is hardly an issue). The reason for this choice is that it removes the need for an expensive tracking generator that is tuned to any specific frequency. You don't need to know the frequency, you merely need RF power to peak at a tuned frequency.

So, the process is simple. You turn on the noise bridge, tune your tuner or Loop, and turn the noise bridge off. Listen to the tuned frequency.

You can do the same thing with background noise, but a pink noise source usually presents more power at any frequency thus giving you a more positive peaking adjustment. With the MFJ Loop's tight bandwidth, this can make a difference if you are not patient and haven't taken the care to keep a log of settings vs. frequency.

If you are inclined to build your own, a simple noise generator can be built out of a battery, resistor, coupling capacitor, and Zener diode.

There are better noise sources, and more expensive too. Most of the cost is in assembly labor and packaging but I would guess the commercial unit runs about $40. As already suggested, you could also tune known stations with large signals and note the tuning settings for future extrapolation. Often, this and patience is enough.

Please can we remember (again, again, again) that the Bird "wattmeter"
is not really a power sensor.

In thinking about this whole problem, it's vital to understand - and
remember - that the indications of a Bird rely on the very theory of
standing waves that is being picked apart.

That means it's part of the argument, not part of the answer.

If there's a downloadable manual, the values may be in the parts list. Then you can plug the values into one of Reg's programs and see what range of impedances you could match.

There's also a program called AAT that comes with the ARRL Antenna Book and automatically sweeps over a range of different loads, and maps out tuner the resulting values of overall tuner efficiency and the power dissipations, voltages and currents that stress the individual components. (I believe the latest Antenna Handbook may have a Windows version, which may provide maps that are easier to read than a big ASCII printout.) Some of the results are scary. For example, if you have a typical low dipole for Top Band, and want to T-match it to your legal-limit amplifier, then be very afraid...

The other part of the problem is to know what impedances you are trying to match. Something like the MFJ-259B/269 will tell you that.

So, yes, the tuner manufacturers could help by clearly publishing the component values. But until you also have all the other information - and have learned how to interpret it - then Reg is absolutely right: you have to buy on faith.

Well, almost on faith. A comparative review of five high-power tuners in QST for February 2003 makes a brave attempt to get into the complexities. There may be extended review data on the ARRL members-only site.

Summarising from earlier discussions about all this, three worthwhile rules of thumb are:

* Before buying, divide the manufacturer's published "power rating" by 3... and the number you get is still only a guide. It cannot be guaranteed because the manufacturer doesn't know how you'll try to use (or misuse) the tuner.

* So don't misuse your T-match. Always use the *lowest* possible value of inductance that will give a match (higher inductance wastes power inside the tuner, and may damage it).

* Don't try to match extremely low or high impedances.

BNC or N are also standards all over the world. So is C, however it is a bit
tricky to find.
PL-259 is hardly useable above 50MHz, and totally worthless above approx. 300MHz
(why PL-259 is the standard for 144MHz rigs is definitively beyond my
undersanding- for
commercial 80MHz LMR, BNC or C is standard, depending on power output).

Richard,

I have set up a SGC with a dipole - basically its screwed to the chimney stack, with approx 50 foot
equal length legs going down to approx 10 feet off the ground, in an inverted V sort of appearance.

Its the best aerial I've ever had !!

Tunes all HF bands (inc 160 and 10) and makes for a pretty discreet system. For a quick easy and effective system on all bands it seems hard to beat, and
no TVI - because its balanced, I presume!

Nick

> Enough challenge?

What a strange coincidence..., I had the same thoughts and almost used
the same words when contacting Dean Straw for an evaluation copy of
his latest HFTA terrain analysis software, to figure out if it was
possible and if it would be worth the effort to interface with this
software to optimize over a specific terrain profile and/or interface
with the VOACAP propagation prediction software.
I also took a look at TA and to see how this would fit, but because
this package is DOS based I decided to take a further look at HFTA.

However, it seems both packages are restricted to the use of
horizontal polarized (Yagi) antennas only. Because 4nec2 was created
to support also other types of antennas (there are already a number of
Yagi optimization programs) it looks like both programs would not
match completely. Furthermore, I am not such an (antenna) expert that
I can create the equations my own to determine the resultant radiation
pattern over none-flat ground for both vertial and horizontal
polarized systems. Also concerning the user-interfrace for both
programs it seems not that easy to automatically interface with one of
them.

So maybe all this will "time-out" till the long winter evenings...

Arie.

Nice suggestion. However I did not write my own nec-2 core, just used
the existing nec-2 sources and changed it a bit to integrate the nec-2
calculations and the sommerfeld ground calc's.

However there is another freeware program available which uses the
nec-2 and for which it is possible to specify insulated wires. From my
memory, I think I saw this on Ray Andersons 'unofficial nec' pages.

> I believe NEC4 can accomodate
> that and could serve as an example how to do it.

One of my great wishes would be nec-4 becoming (public) available for
none american citizens. However I am already waiting for it some four
or five years, and I have no indications this will change soon.

> Also different material for elements within antenna, like copper (insulated)
> wire quad and aluminum Yagi elements.

4nec2 makes is possible to use almost any nec2 card. So there is no
provblem specifying different materials for different parts of the
antenne or for the antenna as a whole. When using the CAD style
geometry editor, one has predefined list-boxes available with common
materials.

> That's it besides transducer for the brain to "see" the design in my head and
> optimize/model it in 3D :-)

During optimization you can see the 3D model change, as it is updated
every iteration (if this is the right english word for it..).

Arie.

Somehow I managed to let my first reply on this subject disappear
completely, so let's give it another try....

***

4nec2 was based on the 'standard' nec-2 core for which I only merged
the separate nec-2 and sommerfeld executables into one single
executable file to be able to use 'sommerfeld ground' inside a
frequency sweep.

The original nec-2 sources contain no provision to handle insulated
wire, but I beleave on www.qsl.net/wb6tpu/swindex.html there is
another freeware program available for handling insulated wires with
nec-2.

> I believe NEC4 can accomodate
> that and could serve as an example how to do it.

Yes. One of my great wishes is nec-4 (sources) becoming available for
none-american citizens. I am still waiting for this some four or five
years but I am afraid I will have to wait at least another 4 years.

> Also different material for elements within antenna, like copper (insulated)
> wire quad and aluminum Yagi elements.

4nec2 supports most of the nec-2 cards, so it is no problem to specify
different materials for any part of the antenna oR for the structure
as a whole. When using the CAD based geometry editor a pre-defined
list of common materials is available.

> That's it besides transducer for the brain to "see" the design in my head and

(Somehow, yesterday I managed to let my reply(s) disappear completely,
so let's give it a second try....)

***

Yuri, what a strange coincedence. This because I exactly had the same
thoughts.

I must admit however that I am not such a (theoretical) antenne
expert, so I think it's a bit too much effort to create the equations
for terrain analysis myself. That's why I already took a look at both
the K6STI program and Dean Straw's latest HFTA program, (both created
to do terrain analysis) and to investigate how much effort it would
take to interface with one of them.
When looking at these programs I realized however that both of them
are limited to horizontal polarized ((stacks of) Yagi) antennas.

4nec2 on the other hand was created to model/optimize any kind of
antenna- structure. (because of my main interes in the lower HF bands
and because there was already enough Yagi specific freeware available)
Furthermore the user interfaces for both programs are a bit difficult
to programatically interface with, so I am afraid this 'project' will
have to wait a while till the long winter evenings...

> Enough challenge?

Yes, that's just what I was looking for.

Source record: 111786
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I'm building a balanced line antenna tuner and have settled on link coupling in order to eliminate the balun from the circuit.

I have a big rotary inductor out of an old Murch 2000A and would like to use it as the output link. I've decided on a variable (tapped) input link. I'm wondering if anyone has done this and what technique they used to mount the input link (i.e., how to get it close enough for effectively coupling).

Without going through their catalog, the only loop I am familiar with is their amateur magnetic loop- whose response from memory goes down to perhaps 30M- but not below. Is this the loop you are considering, or do they now make a SW receiving loop?

TCARC Hamfest 2003 Scheduled for Saturday, August 2, 2003

ITHACA, NY The Tompkins County Amateur Radio Club announces the Finger Lakes HAM-IN (hamfest and fly-in) at Tompkins County Airport (KITH), 3 miles NE of Ithaca on Route 13, on Saturday August 2, 2003.

Talk-in on 146.970- AF2A repeater.

Vendor setup starts at 6 AM (inquire for Friday night setup time).
Doors open to the public at 7 AM Saturday morning.
Hamfest closes at 2 PM Saturday afternoon.
Large hangar for indoor vendors and displays.
Drive-in setup.
Paved outdoor flea market and parking.
Aviation displays - fly in and show your plane for free!
Breakfast and lunch served by Boy Scouts.
Admission: $5.00 at the door
Indoor tables: $10.00.
Outdoor space $2.00 each.
ARRL sanctioned event. VE exams starting at 9AM, walk-ins always welcome at tests.

More info, including a PDF format flyer from a previous year, is available on the club
website at
http://www.compcenter.com/~tcarc/

For more info email Mike N2VR at n2vr@.nospammerslightlink.com
after removing the NOSPAMMERS and leading period.

Arie
As a retired person I do not have enough time for a lot of things so
as yet have not looked at your program. (Old people have so many
projects but always under estimate the time required because
abilities deteriate as age progresses)
Could you tell me if you have the ability to make an impedance value
a variable which could be helpfull when designing loops?
Also, how many variables do you have available together with max
number of pulses used ? Since close coupling of wires can be very
sensitive to change, to me the above factors would be all important.
I would add however, that coupling is not viewed seriously in ham
radio so attempts to provide such features would provide little if
any reward.
Again thank you for all the work you have done on a sharing basis
to keep this hobby so interesting
Regards
Art

Tune it for maximum noise or signal on the frequency. You should hear
the motor noise on your receiver as the capacitor turns. Then fine
tune it back and forth.

One of the most serious and persistent problems you've had in communicating your antenna ideas is your insistence on creating and using your own unconventional definition of efficiency. As I've pointed out before, and to no effect, is that the term has a universally accepted definition with regard to antennas. As long as you continue to make up your own definition, you'll increase your difficulty in communicating your ideas. But it's a choice you've made.

I ran my ALINCO autotuner (meant for an end fed wire) that way for a couple of years. I hooked the ladder line to the "antenna" and "ground" connections. I second the motion for the chokes on the Feed and control line back to the shack. I actually had the tuner in the shack for a while, and did not notice any difference with rf when I moved it out of the shack. In both cases I had some RF on the Coax and the control lines which the chokes cured. I used a heavy ground for lightening protection.

>

I agree with you that the field is first converted by the antenna
before it can be measured.

But by definition, the E field is definitely related to voltage
potential.

Hugh Skillings' Fund. of Electric Waves: "Voltage from point 1 to
point 2 is the line integral of the electric field along any path from
point 1 to point 2. This is the amount by which point 1 is at a
higher potential than point 2."

Say PD = E^2/Z0 = H^2 * Z0. If you say the Power Density =
V^2/(R*m^2), and the R=Zo, then these will cancel, giving you E =
V/meter, which are the correct units. So here we are equating the
impedance of free space will a resistive impedance or load.

Roy, what do you think 1uV/meter really means in terms of how you
measure it? I mean, under what conditions must you have to measure
this 1uV/meter?

I'm starting to think that what this really means, is that an
exploring particle with a unit positive charge, when placed in a
electric field of 1uV/meter, will experience a change of voltage
potential of +1uV when it is moved directly towards an isotropic
radiator ("the potential of a point in space is the work required to
move to that point a unit positive charge, starting an infinite
distance away...potential increases as one positive charge is moved
closer to another positive charge" - Skilling).

> Good thing, too. Otherwise we'd all get electrocuted by the Earth's 100

One could define far-field as the point where the E-field/H-field ratio
is and outward continues to be 377 ohm resistive.

The IEEE Dictionary defines "far-field region - The region of the field
of an antenna where the angular field distribution is essentially
independent of the distance from the antenna."

First off no one is forcing you to do CW. If you don't want to do it...then
dont. On the other hand many of you non cw types are forcing the rest of us
to lose CW. So who is doing what to whom???

As for the music and CW. Correct. Makes it much easier. Its the rhythm
that does it.

Tap your foot to a 4 x 1 cadence. Then tap your finger on the desk in
sequence with it. Tape it three times and you have a "S" tape it four
times you have a "H" tape it five times you have a "5".

Now do this. Keeping the foot going. Send a "V" di di dit dah.
Keep in cadence. See the rhythm ? great ain't it ?

On the Textron C band and S band antenna range[s] that I managed we had
a practical, that is PRACTICAL, limit of 1000 wavelengths to establish
the far field pattern. I don't know if it is/was technically justified
but it was contractually defined.

Right, just tune for max. noise or signal, please notice that some loop,s
are
very sharp and have a very small bandwidth. And if you can hear the motor
turning the capacitor, then return the antenna to the manufacture and tell
him to design his products properly.

Regards Max

What? "many of you non cw types are forcing the rest of us
to lose CW"

If the CW requirement is gone you can still do CW.

Who is forcing who? Is someone being forced when CW is a
requirement, or is someone being forced when someone else
believes that the CW requirement should be dropped?

Roy, the die was cast years ago when anything "new" was trashed
without a hearing. I now accept that all is now known about antennas
except the really deep things that Cecil is so bravely pushing on with
where I failed.
Even if I was to demonstrate succesfully a different antenna I would
have as much success in persuasion as the U.S. Government is having at
home and abroad.
Just forget about my antenna and go with the common consensus that it
can't possibly be true since I have no credability. I now feel
comfortable with that analysis and expect that the back biting will
gradually go away as I conform with the crowd. Having a great time ,
My personal delight a Merc diesel has moved over the 1/4 mil mark and
I will keep it running for ever, even tho the wife bought me a Merc
diesel replacement for appearances sake which is why it has only 26K
miles on it since 97 and the miles on my beuty keeps getting higher.
Had the cylinder compression tested a while ago and it still matches
new specs !
Having a lot of fun with antennas especially watching two signals
merge on the S.A. as factors are changed together with change in
coupling.

OOOOOOps

I used that word "coupling" again,,,....I must go and wash my
mouth!
At least I am well equiped when winter arrives to ensure that I have
plenty to do.

Hi Dave,

That was more for collimation than field Z characteristics. By 1000
Wavelengths you are in the Far field 100 times over; but when out 10
or 100 wavelengths, this still presents the antenna as a non-point
source. When links are built with short distances between identical
antennas, the computed antenna gains are often off significantly.
Same antennas pulled back will begin to exhibit expected, computed
gains.

Actually it is the digital signal pulsing the motor that is so easily
picked up. It's pretty hard to get rid of!

your premise is flawed because you do not take into
consideration the entirety of ham radio. ham radio is
what it is because it is filled with a rich texture of history
and experience. Like the Kentucky Derby and
Wimbleton , for example. There are plenty of horse
races and tennis tournaments , but only one " ham radio.
(is this too complicated for you ??) The first attempt at a
codeless radio license resulted in Citizen's Band. Popular
in the '70s but wasted away to what it is now ... and include
the newer citizen's bands into this too. This , plus many people
are frequently too LAZY (or poorly motivated < yourself perhaps >
to continue the rich tradition of morse in HR) and eliminating the
morse requirement would " definitely " force the eventual end of
CW on the bands.
There are PLENTY of non morse opportunities , currently , in ham
radio (too many for my tastes) .... taking away the morse
requirement completely , would mean the end of the rich tradition of
hamming and rob everyone (that comes after) of the history and rich
experiences that morse can bring. (ever heard of " wolf hung ???
I doubt it ...!! understanding the spirit of woulf hung resolves it
all)
Ham radio without morse is NOT REAL hamradio ... it's " radio "
minus it's rich history and texture of life.

there I said that ......

dusty
k4nlz

morse is joyous and something EVERY serious ham radio enthusiast
should learn the love (of radio) with-in . the ethereal bliss of
morse communication " cannot " be merely spoken of , it must be "
personally " (internally) experienced to be fully appreciated.
traditional " ham radio " is NOT really ham radio without it. if
you have experienced this bliss personally , you understand
completely , if NOT ... you do not fully appreciate ALL that ham
radio offers. either you " have , or you are still not " there "
yet. there is FAR more to morse than many people appreciate or
understand ... I highly recommend that you experience it for yourself,
completely , ... then YOU will understand also. (and be MUCH
richer for the experience)

In the AES catalog, the ma5v is rated for 20-10, the ma6v is rated for
20-6. Maybe there is some overlap of instructions on the two units.

In the pictures, the ma6v appears to have a vertical element that is
missing in the ma5v.

One slight correction, Art. Because of the similarity between light and radiated EM waves, most things about antennas are known, at least to the limit of the models to handle reality.

However, it appears to me that some things have been overlooked when the coherent EM waves are confined to a one-dimensional transmission line. Those things that have been overlooked are what I am pursuing and as far as I can determine, they happen only inside a transmission line or at a thin-film non-reflective surface using coherent light waves. That's what makes it special.

That is not to conclude that you haven't discovered something special, just that my focus is Z0-match points inside transmission lines and non-glare thin-film coatings involving orthogonal coherent light.

Step One:
Find an unused pirate (preferably FM).

Step Two:
Make feedline connections to pirate.

Step Three:
Feed signal to pirate.

It might be, but the picture is still pretty poor... makes it hard to tell
just how good the solder job really is.

I am really happy with the HyGain TH3MkIV. At 40 feet it is a bit low for
20, but still works well. My first hour on 15 SSB got me China, Mongolia,
and Thailand from NE US. I think it just makes your radius.

Ian, G3SEK wrote:
"---the Bird "wattmeter" is not really a power sensor."

The Bird wattmeter indicates the watts, joules per second rate at which energy flows, well enough to be accepted as a world standard portable instrument.

Denigrating the Bird is specious because my statement, "Your Bird wattmeter will show a forward power but no reflected power---." is true! The statement only requires the right Bird element to indicate the presence or absence of energy flow in one direction or the other. The Bird is eminently capable.

I used the bird because those familiar with it are confident in its ability to separate forward power from reverse power. IEEE defines power as energy in motion, so it could be in perpetual circulation and never used, but it is still power when the volts and amps coincide.

Best regards, Richard Harrison, KB5WZI

Cecil, W5DXP wrote:
"What causes the match? The cancellation of reflections."

This is like Abbot and Costello. You got it! Who`s on first!

You have a source which only delivers energy at a certain volts to amps ratio, period!

You have a load which only accepts energy at a certain volts to amps ratio, period!

When the above ratios are in fact identical there is no problem. When the above ratios are different something has to give and it isn`t either ratio, Zo or ZL. Instead, the load takes what the source can deliver and rejects the surplus volts or amps whichever is the case, as are created by ZL, and the limited deliverability created by the Zo. The surplus generates a reflected wave as Cunningham recounted with his description of missing inductance and capacitance in the missinng continuation of the transmission line (A short on the line vitiates the capacitance etc.). The explanation is logical and I recommend his broadcast antenna book.

What`s not to understand about matching? When the load is not matched, you add the incremental receptivity required to take the surplus current or voltage at the load, so that the load, and the stub in Terman`s example, are a perfect match and there is no longer any surplus to be reflected. The impedance of the load has been adjusted, by the addition of a stub in Terman`s example, to Zo. Terman says the wave from the stub cancels the wave from the mismatched load. No doubt a shorted stub makes a reflection. The reflected volts from the stub are exactly equal and opposite to the reflected surplus volts from the load at the junction, and Terman says there is no reflection toward the generator.

I never won an argument with Terman, though I tried. I believe there is no reflection past the stub back toward the generator. If so, and it certainly is so, I`ve put those stubs out at the antenna myself and they create a match when adjusted properly, the energy on a lossless line will be the same at the generator and anywhere on lhe line. It`s flat.

Best regards, Richard Harrison, KB5WZI

> There is no broadcast television in the HF bands. Channel 2 is 54-60 MHz,
> low VHF...but that part of the band (up through channel 5) is also within
> the scope of BPL frequencies..

But the motive still holds. Have you noticed that the ARRL is
collaborating w/the bpl providers to place the interference on SW bands,
where it will have 'optimum' impact on AM transmissions, rather than
placing it on VHF bands, such as 6 metres, or the FM broadcast band,
where the interference would have less of an effect, in relative terms?

Obviously, such a strategy will help to clear out the low-rent tenants
currently cluttering the U.S. SW spectrum, so it can be gentrified for
a better class of paying customers. On the ARRL website there's an
article of one use for BPL which explains why they aren't designing
asymmetry into it: the ability to hook appliances into the web. You've
probably heard of Coke machines hooked up to the internet. Imagine
a frige that can read the RFId tags of products inside it, and can
transmit that data to your local Safeway. They wouldn't want to
restrict uploads for those kinds of uses.

There are also trucking companies that want to get exclusive use of
HF spectrum to track their shipments.

Great. If you could now only work in Roswell, grassy knoll, Elvis, moon landing hoax, the CIA and the Jews, you'd have it made.

BPL is bad enough without idiotic conspiracy theories.

One caveat about modeling collinear phasing stubs with EZNEC or other NEC based programs: The stubs do radiate, so you can't use transmission line models for them -- doing so results in some pretty seriously wrong answers. You have to use wires to model the stubs. If you do, you can get accurate results.

For my fancy stereo, I use a cheapo FM dipole lying on the floor, and
a cheapo AM loop. Pulls in stations nicely in this metro area.

Since the *other* radios in your house work, I'd take the thing back,
get a refund, and buy something else. If they ask why, turn the thing
on and let them try to tune in a station.

You must be a lifetime member of ARRL, eh? And you would snip the
reference to the article at ARRL's site on other uses for bpl,
giving details on how it is collaborating in the bpl effort, eh?
It 's typical of scum like you to make such an attack, since you are
too lazy to look up the fact that there was a coke machine on the net,
the 1st one in Pittsburg. Glenn Hauser had a report on a trucking
company testing HF tracking (or perhaps a reference to Kim's show,
when it was still on VOA). It's nice of the scum at ARRL to give
free consulting services to those who have more than enough time &
money at hand to trash the SWL bands.

Sorry, Richard, but what is it about the following simple points that you're so stubbornly determined not to understand?

0. The practical usefulness of a Bird wattmeter is not in dispute. I have never denigrated the practical usefulness of the Bird - like thousands of others, I own a Bird 43, use it all the time and wouldn't be parted from it. But its *practical* usefulness is not relevant to the following three points about transmission-line *theory*.

1. The Bird "wattmeter" does not in fact sense power. At the detailed level, it senses voltages and currents in its internal transmission line, and then sums and subtracts them to give RV voltages that the diode detects. I repeat, there is no sensing of power as such, and no detection of power as such.

2. It only indicates power due to its calibration. The calibration into a matched load (no reflections) is not in dispute. But with mismatched loads you need the help of transmission line theory to interpret what the "forward and reflected power" readings actually mean.

3. But in this discussion, transmission line theory is under question. Because the Bird's forward and reflected power indications rely on that theory, they logically cannot be used as external evidence of what the forward and reflected power flows really are... or even whether they truly exist.

So, I stand by exactly what I said: When discussing transmission-line theory, the Bird's indications of forward and reflected power are (in short) "part of the argument, not part of the answer".

The energy and momentum in EM waves, particularly, the energy and momentum in the wave reflected from a mismatched load. What happens to that energy and momentum? We know it joins the forward wave. How does that energy and momentum get reversed? A virtual impedance is a result and not the cause of anything.

> The reflected volts from the stub are exactly equal and
> opposite to the reflected surplus volts from the load at the junction,
> and Terman says there is no reflection toward the generator.

I'm not arguing that point. What happens to the energy in the two waves that have their voltage and current amplitudes equal in amplitude and opposite in phase? There is no doubt those waves cancel and there is no reflection toward the generator. But what happens to the intrinsic energy that pre-existed the cancellation event?

> I never won an argument with Terman, though I tried. I believe there is
> no reflection past the stub back toward the generator.

No argument about that. The question is where did the energy and momentum go when those two waves were canceled thus eliminating reflections back toward the generator. Waves can be canceled. The energy in those waves cannot be destroyed.

Ian, if you can provide an example of standing waves (in a single source, single feedline, single load system) without forward and reflected waves, you can indeed discredit the Bird wattmeter. If you cannot, it seems that forward and reflected waves indeed do exist and the Bird wattmeter design is based on a valid assumption.

Ian, G3SEK wrote:
"1. The Bird wattmeter does not in fact sense power."

The speedometer does not measure miles nor hours, but it can satisfactorily indicate miles per hour. So, what?

"2. It only indicates power due to its calibration."

Without calibration most instruments only serve as crude indicators. The usual Bird is calibrated for a 50-ohm line which enforces its Zo. Use the common Bird in a different line and its calibration is off.

"3. But in this discussion, transmission line theory is under question."

I suggested using the Bird as an indicator of transmission line / load match, period. This is based on balance in the directional coupler which is usually good by design and factory adjustment. Many Bird users have adjusted their lload matching networks for minimum reflected power indication.

My allusion to the Bird was meant to show that it makes no difference if you have two equal and opposite waves traveling in the reverse direction on a line or no waves in that direction at all. A Bird wattmeter operating properly should indicate zero reflected power.

Best regards, Richard Harrison, KB5WZI

Cecil, W5DXP wrote:
"How does that energy and momentum in EM waves particularly the energy and momentum in the wave reflected from a mismatched load (get reversed?)"

I recall being instructed about the "Ferranti Effect" which doubles the volts at the end of an open-circuit line, and its corollary, doubling the current in a short-circuited line. These, using line capacitance and inductance are shown, as Cunningham does, to launch a wave in the reverse direction, a reflection. Less extreme mismatch produces smaller reflection.

A discontinuity in Zo causes reflection on a transmission line. Impedance variations, including virtual repetitions of opens or shorts, occur at cyclical distances back from a discontinuity. The volts, amps, and impedance anywhere back from a discontinuity create a vector sum of the incident and reflected waves. Sums of the voltages and amps create voltage and current standing waveforms. The incident and reflected waves themselves are quite steady. Standing waves are more form than substance but have their effects.

Cecil also wrote:
"What happens to the energy in the two waves that have their voltage and current amplitudes equal in amplitude and opposite in phase?"

These two waves continue to circulate. One in the short length of transmission line between the mismatched load and the stub placed on the line to correct the mismatch. The other continues to circulate in the stub. This circulation is established during the transient period and continues until it is disestablished. The reflection which would have prevailed on the line between the generator and the stub junction with the line, were the stub not there, is simply absent. The line sees a combined load plus stub impedance at their junction of Zo.

There is no reflected wave in the line in the length between the generator and the stub junction with the line. So, there`s no extra energy to be accounted for.

Best regards, Richard Harrison, KB5WZI

As a data point, Using Bird wattmeters, the reflected power was subtracted
from the forward during the 75m mobile shootouts to determine the power
delivered to the mobile antenna.

I'm a Libertarian. Libertarians believe in the least amount of governmental
intrusion and control as is necessary. For instance, Libertarians are against
seat belt laws, motorcycle helmet laws, and I assume also against unnecessary
governmental requirements like a driver's test using a stick shift and Morse
code. I suspect that the new hams who learn Morse code because they want to
will be better members of the ham community than the ones who learned Morse
code because they had to even though they hated the idea of being forced to.
I suspect they will certainly not bitch about Morse code testing 24/7.

But that is not what happens when two waves cancel. For an idea of what happens, please reference Reflections II, page 23-8,9. If the two voltages are 180 degrees out of phase and the two currents are 180 degrees out of phase, neither one of them can double. Calling that a virtual short or virtual open is incorrect, IMO.

I forgot to say they are traveling in the same direction and that they are coherent. The two waves disappear from existence. What happens to the energy they contained?

Yes.

or a attack on the Morse testing requirement?

Yes.

In the back of your mind, you realize that the usefulness of CW is low
enough that the majority of people will never bother to learn it if not
forced to do so. CW, as a requirement, will be dropped. We will then see
what value peopls put on it.

That's utterly dishonest quoting. You should be ashamed of yourself.

You are perfectly aware that earlier in the same message, I said:

>1. The Bird "wattmeter" does not in fact sense power. At the detailed
level, it >senses voltages and currents in its internal transmission
line, and then sums >and subtracts them to give RF voltages that the
diode detects. I repeat, there >is no sensing of power as such, and no
detection of power as such.

My point is that all directional couplers DO work by sensing forward and
reflected waves of voltage and current BUT NOT WAVES OF POWER.

The inner workings of every directional coupler can be explained
completely in terms of waves of voltage and current. That includes
resistive bridges, Bruene bridges and parallel-line couplers (of which
the coupler in the Bird is a sub-class). They all work because E and I
waves are phasors, and the construction of the coupler makes them add in
one direction and subtract in the other. There's an example of a
detailed analysis, about the Bruene bridge but applicable in principle
to other types as well, at:
www.ifwtech.co.uk/g3sek/in-prac/best-of.htm#bruene

Waveguide directional couplers work in very similar ways, but have to be
analysed in terms of forward and reflected E and H fields. That kind of
explanation also works for a waveguide circulator, the difference being
that some of the fields are inside a magnetic medium. A coaxial
circulator is more complex because it involves voltages and currents on
the line part and also E and H fields in the magnetic medium, but the
principle is the same.

This is all standard stuff that has been known for decades. Forward and
reflected waves of V and I (or E and H) give a complete explanation of
the directional properties of all such devices.

Let me turn the question around, Cecil: can you explain in detail how
any directional coupler gets its directional properties, using *only*

your concepts of power waves?

This was confirmed at the bench by my example of a mismatched source
feeding a mismatched load (creating this characteristic of circulating
energy in a purely resistive network) illustrating the Mismatch Error
in the thread:
"The Cecilian Gambit, a variation on the Galilean Defense revisited"
This characteristic is also borne out by the necessity of having low R
components such that each successive pass of the circulating energy is
not power lost to that Ohmage.

Hi Bob,

Stapled to what? Untreated wood? In the rain? THAT would look like
a fair sized resistor hung on the line. Insulate the staples? You
still have the same resistor now capacitively fed. Would you notice
with either circumstance? Odds I would offer is 50:50.

Are you the type to chase down the last 1dB? You would have to squint
hard at the S-Meter to see it. If you chase below 1dB, switch to
ceramic standoffs.

> You must be a lifetime member of ARRL, eh?

And you must be using Madame Cleo, because your psychic readings are
worth shit.

> And you would snip the
> reference to the article at ARRL's site on other uses for bpl,
> giving details on how it is collaborating in the bpl effort, eh?

And you would completely and intentionally misinterpret the ARRL's
anti-BPL position as the opposite, implying they actually "collaborate"
with the BPL industry in some huge conspiracy that is clear only if one
wears an aluminum foil hat.

> It 's typical of scum like you to make such an attack, since you are
> too lazy to look up the fact that there was a coke machine on the net,
> the 1st one in Pittsburg.

It is typical of a conspiracy theory nut like you to invent all kinds of
government conspiracies that have no basis whatsoever in reality except
for people who buy a shack in Montana and arm themselves to the teeth
for that inevitable day when the UN-based world government (ATF and IRS
included) tries to knock down their door and suppress their "God" given
freedom to be stupid.

> Glenn Hauser had a report on a trucking
> company testing HF tracking (or perhaps a reference to Kim's show,
> when it was still on VOA). It's nice of the scum at ARRL to give
> free consulting services to those who have more than enough time &
> money at hand to trash the SWL bands.

Glenn Hauser, Kim, Hewey and Dewey, Ben and Jerry, who the hell cares?
Your so-called ground-breaking earth-shattering Pittsburg (sic) Coke
machine is a red herring. Internet appliances concept has been around
for years. You have yet to show just how is "ARRL collaborating w/the
bpl providers to place the interference on SW bands".
You have yet to show just how "such a strategy will help to clear out
the low-rent tenants currently cluttering the U.S. SW spectrum, so it
can be gentrified for a better class of paying customers". Who are these
phantom paying customers who are taking over SW? Trucking companies? Do
these trucking companies have a secret anti-BPL filter that they will
deploy once they take over SW? Another conspiracy?
When you attempt to quote "an article on the ARRL website", it is a

common practice to provide a link so that people can read it themselves, instead of relying on your interpretation of "asymmetry".
You also have to show just how is the ARRL collaborating with the BPL industry in the rest of the world, because there, too, is the BPL placed directly across the SW spectrum. Could it be that this is the optimum spectrum for data transmission over the power grid that is not designed to transmit data? Naaaaah, it must be a (world-wide) conspiracy!!! And the ARRL is in on it!!!

In short, your post is a typical example of a conspiracy nut and it does nothing constructive to help with the anti-BPL effort. On the contrary, it completely muddies the issue while providing the pro-BPL people with the ammunition to label hams as lunatics.

So take your anti-ARRL paranoia to your Freemen CB meeting in your Montana shack and leave it there.

Sure, P=V*I and V/I=Z0 for both forward waves and reflected waves. The
angle between the voltage and current is always zero degrees or 180 degrees
for any traveling wave. The ratio of voltage to current is always Z0 for
any traveling wave.

> Help! Please!

You can make a 1/4 wave vertical antenna very easily. If you only need it to work for a short while, then you can use cheesy materials as follows:

Get a UHF panel mount receptacle, SO-239. Find some brass rod that will fit into the solder lug on the connector. you will need about a 30" length of this for the element. The formula is length(inches) = 2800/freq(MHz). Solder the rod into the connector's center pin.

Drill the necessary five holes to mount the connector in a brass sheet that's available at hobby stores. Use .031" or .062" thick brass. Then solder four 36" lengths of brass rod to the plate, fanning out horizontally in four directions, to make ground radials for the antenna. Bend each radial downward about 45 degrees.

You can mount the antenna by bolting some angle iron to the brass plate, and drilling holes for a mast clamp in the vertical part of the angle iron.

This antenna will be about 50 ohms.

Take a look at http://home.tbbs.net/~bhammond/FM_ANT/ to see how it's done.

The next type you could consider is the "j-pole". Again, this has an unbalanced 50 ohm match (if constructed correctly), and is quite easy to attach to a mast. http://www.hamuniverse.com/jpole.html is a handy calculator for getting the length right.

A quick Google search for antenna types would definately help you out!

Just playing devels advocate here, but, as you state "If you put X watts into one antenna and extract Y watts from an antenna coupled to it, and measure the efficiency of the "transformer" the same way as you did the conventional transformer, you'll find it has lousy efficiency.", does that refer to the 377 ohms (or so) free space coupling impedence, or could that effeciency be improved by having the antenna's matched radiation resistance approach that 377 ohms? (I.E. max transfer of power is at Z0 (in) matches Z0(out)! or, is this academic for this? Perhaps, better for Dr. Shorza Gitchigoumi of CQ fame, or Larson E. Rapp of ARRL fame (both with bad habit of only presenting articles in the 4th month of the year in their respective publications) ! But, I'd thought I had better ask! Jim NN7K

Ian is precisely correct when he says power meters such as the Bird, or Bruene's Directional Wattmeter DO NOT sense power, they sense only voltage and current. The meter indicating the power is simply calibrated to indicate the E^2/Zo power flowing in the characteristic impedance, Zo, of the line. E^2/Zo = power, and that expression was used to calibrate the meter scale in terms of the voltage and current propagating in either direction. See Page 3-16 in Reflections 1 and Page 3-15 in Reflections 2, taken from Warren Bruene's QST article, April 1958, Ref 38 in Reflection.

> virtual open is incorrect, IMO.

Cecil, this is the error on Reflections that I told you about last week when you cited the above reference in Reflections. I inadvertantly called the effect a 'short circuit', while it is actually an open circuit. If a 3rd edition of Reflections is ever printed this error will be corrected. Now when two waves interfere with their voltages 180 degrees out of phase, but with their currents in phase, we have a short circuit. Either of these conditions occur at the matching stub point, depending on the resistance component of the load impedance and the distance from the load to the stub point.

I thought it was common knowledge that the reflected energy is totally re-reflected in the forward direction when encountering the open or short circuit at the matching point.

Ian, G3SEK wrote:
"What are those V`s and I`s doing in your reply?"

Cecil is right on target. Power is VxI. The Bird takes carefully balanced samples of V&I. In the incident wave the samples are in-phase. In the reflected wave the samples are 180-degrees out-of-phase. By exactly balancing the two samples, the reflected wave cancels. Only the incident wave is sensed. To sense the reflected wave only, the polarity of one of the two samples is switched.

I am now more dangerous. Until today, I had never seen one of Kraus` books. I now own the third edition of "Antennas (for all applications)". Kraus says there are "fundamental" units and "secondary" units. The "Ampere" is a fundamental unit. All secondary units can be derived from the fundamental units.

In the Bird, the given is a 50-ohm line. Power is 50(I)(I), since I=E/R = E/50, and E = 50(I) = V.

Power = EI

The Bird is accurate enough using a sample of E and a sample of I and scaling to determine power. Multiplication is just scaling or the number of times you repeat a number in an addition column. In the Bird, scaling is an electrical adjustment.

Best regards, Richard Harrison, KB5WZI

Ian, G3SEK wrote:
"1. The Bird "wattmeter" does not in fact sense power. At the detailed level, it > senses voltages and currents in its internal transmission line---."

Since the ratio of voltage to current in either direction is always Zo, all you need are voltage and current samples of one direction at a time.

The Bird is not alone in determining power from such voltage and current samples. The dynamometer does too.

A d-c meter is useless on a-c because the needle tries to move first one way then the other as the a-c current through it alternates. Inertia keeps the indication on a-c close to zero.

The dynamometer eliminates the flicker and gives an appropriate deflection on a-c. It does this by replacing the d-c meter`s permanent magnet with an a-c coil. This is arranged to torque the needle upscale no matter whch direction the current takes through the coils. The moveable coil is always deflected the same way by interaction with the fixed coil.

It is simple to calibrate a dynamometer for power and feed current through one coil and place volts across the other. It senses volts and amps but it reads out power, as does the Bird wattmeter.

Best regards, Richard Harrison, KB5WZI

Quoting from the article on my web page:

"Note that this is NOT a new and different method of system analysis.
The only purpose of this paper is to illustrate how to track the
energy at an impedance discontinuity point in a transmission line."

It does so by recognizing destructive interference between two phasor
voltages when the relative phase angle is greater than 90 degrees and
the constructive interference between two phasor voltages when the
relative phase angle is less than 90 degrees.

There are lots of questions that cannot be answered by any discussion
of power only. My *ONLY* purpose is to track the energy components
which is in addition to standard system analysis. There is absolutely
no conflict between the two subjects. The energy components are always
associated with voltages and currents.

Walter Maxwell wrote:
> I thought it was common knowledge that the reflected energy is totally
> re-reflected in the forward direction when encountering the open or short
> circuit at the matching point.

The voltages and currents are listed at the Z0-match point in the following
example:
rho=0.5
200W source---50 ohm feedline--+--1/2WL 150 ohm feedline---50 ohm load
Vfwd1=100V--> Vfwd2=200V-->
Ifwd1=2A--> Ifwd2=1.333A-->
<--Vref1=0V <--Vref2=100V
<--Iref1=0A <--Iref2=0.667A

Vref1 = Vfwd1(rho) + Vref2(tau) (this is the same as b1=s11*a1+s12*a2)
0V = 50V at zero deg + 50V at 180 deg i.e. the voltages cancel

Iref1 = Ifwd1(rho) + Iref2(tau)
0A = 1.0A at 180 deg + 1.0A at zero deg i.e. the currents cancel

Through wave cancellation, both the voltage and current go to zero in
the direction of the source. That's like a short for voltage and an
open for current.

Wrong. It's perfectly legal to build and own a working high
powered broadcast radio station, you just have to use it only with a
dummy load.

I use mine to keep my bed warm... :)

Direct connection to coax. Do not use ladder line. Do not use a balun.

History indicates quite strongly that most pirates were unbalanced.

Correct. I have said that, or near, several times in this and preceding
threads. An article saying the same has been on my web site for almost a
year.

That is of course true... but if you believe it relevant to this
discussion, you are indeed much more dangerous.

>In the Bird, the given is a 50-ohm line. Power is 50(I)(I), since I=E/R
>= E/50, and E = 50(I) = V.
>
>Power = EI
>
>The Bird is accurate enough using a sample of E and a sample of I and
>scaling to determine power.

As you yourself say, the Bird senses current and voltage samples; and
these are then added (forward) or subtracted (reverse). There is no
physical mechanism inside the Bird by which E x I multiplication takes
place, so power is not directly sensed or measured.

>Multiplication is just scaling or the number
>of times you repeat a number in an addition column.

That is a kindergarten concept that only works for integers (how do you
repeat a number 3.14159 times?) and anyway, it physically does not
happen inside a Bird.

>In the Bird, scaling
>is an electrical adjustment.

No, the meter scale comes from an external calibration.

Wrong. The Bird has no second meter coil, and no other physical
mechanism to multiply the E sample by the I sample.

As Walt says (thank you, sir) the Bird is *calibrated* in terms of power
using a matched load.

I've made my point. There's an Internet abbreviation called
IAFWAFIAWMWQ... so I'll be wise, and quit.

You have already lost the battle.

What can you say against an argument that includes "Homeland Security"?

"Further, the addition of BPL facilities-based technologies will, as
correctly recognized by the Commission, enhance homeland security by
"creating new facilities to provide redundancy."

Has anyone done a grep for 'terror' throughout these documents?

And the fact that BPL has been abandoned for economic reasons in Germany
will probably make the US-guys feel that they can do a lot better than us
stupid Krauts. After all, we lost the war.

Bye bye ham radio in the US.

Given the cost of the mfj loops, over $300, and their limited tuning
range, you might first look at the return policy on the boogers before
ordering one.

I wouldn't be surprised if the active antenna does as well or better.
Or that a wide-range discone, or a random indoor wire with a low-cost
antenna tuner, might be equal or better, at much lower dollars.

You could also check the ARRL Antenna Book for ideas on receiving
loops.

Can someone tell me what the SG-230 ATU does when powered off? Is the antenna left connected / grounded or what.
I want to use one on maritime mobile and will be calling on certain frequencies for mail transfer but in between will be scanning and downloading FAX, RTTY and NAVTEX on frequencies from 490 kHz upward. Transmitting on ham bands 80 through 15 M only. I'm wondering what sort of signal will be passed through the ATU when not in use on the ham bands and not tuned (receive only) and when powered off.

2150. Double bi-quad 2.44 ghz antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-27 15:01:55 UTC
From: Rob <spam@spam.com>
Message-ID: <8QRUa.1668$w4.175168@newsfep2-gui.server.ntli.net>
Source record: 111694

Not being an RF engineer, I need to know the dimensions of the reflector for a double bi-quad antenna for a wireless lan link (two wire bowties placed in front a flat plate reflector - here is a quad bi-quad: http://www.frars.org.uk/cgi-bin/render.pl?action=link&url=1162&goback=1064). This is how I see it (I may be wrong), any wires that have no sheild will act as a radiator, so if the length is a wavelength or wavelength divided by 2,4,8 etc (ie speed of light in air/frequency, 300,000,000ms/2,440,000,000hz = 0.123meters), then the wave is not disturbed and continues along its path. The biquad is a piece of wire 244mm(2 wavelengths) long folded into 2 squares, so I guess you have 8 radiators.
So to connect 2 biquads or patch panels together the wire below would have to be 123mm long and connect to the coax in the centre.
Therefore a double biquad would be 123 x 244mm, but I need someone to confirm this.
The radiator part I think is OK, its the reflector size and raditor spacing I am not sure about.

Cheers

Rob

I'm sorry, but that is incorrect. Refresh your memory on how a slide rule multiplies. Two linear values of length are physically added but a product is read from the results. The secret to multiplying using linear scales is to calibrate that linear scales logarithmically. It's easy to understand for a slide rule, is it not? The same applies to the Bird wattmeter scale.

The Bird takes two linear voltages and adds them. But the power scale on the Bird meter face is scaled logarithmically just like it is on a slide rule. That's why the multiplication scale on a slide rule is nonlinear. That's why the power scale on the Bird wattmeter is nonlinear. The Bird is mechanically multiplying a voltage proportional to the voltage by a voltage proportional to the current. It adds two linear quantities and, just like a slide rule, reads the results out on a logarithmically calibrated scale thus accomplishing the multiplication function.

Richard -

Here are the FAQ from the SGC web site:
http://www.sgcworld.com/products/239/239faq.html#1

Note: this question is in reference to the SG-239 SuperTuner

#1 If I do not switch on the 12 VDC power to the tuner is the tuner always
in the bypass position so the RF goes right through it and nothing is tuned?

At any time12 v is not applied to the tuner, you will have total
inductance 16 mH (microhenry), in series with your antenna.
To bypass the tuner you must:

A) Have 12v applied. Note: If you have 12v applied then coupler would
be on - If no TXMT occurred, it would be in bypass mode.

B) Reset the tuner by tuning 12v DC off then on or with reset or
Smartlock.

Hi Ian,

If you boil down power to heat, it still takes the scale on a thermometer to confirm the magnitude. Scales are a form of quantifying into scientific rigor the qualitative utterances of "not much power," "some power," "more power," "a lot of power...." Denying that multiplication is performed through the observance of established boundary conditions and the movement of a coil in a magnetic field (the resulting torsion which easily conforms to evidence of power) by nay-saying is not compelling argument.

I've seen antennas described as "transducers" and with this current side-topic, the Bird Wattmeter is more so such a transducer in its translation of electrical power to physical power. The Bird Wattmeter consumes power at a known ratio to the applied power. Ratios are one of the simplest and most resolved quantities to confirm. There is very little, short of serious physical abuse, that can disturb this ratio (such as overpowering the line to create breakdowns such that there are destructive arcs or fusing current). Efficiency aside (that power lost to resistors within the sensing circuit), power of a known ratio magnitude is invested in the needle's angular deflection and holding it against spring tension. Newton would easily accept this as "Power." It is basically what he called the ballistic pendulum.

If one cannot measure Power with a Bird Wattmeter, then prayer is the only solution to the enigma of its reckoning. If you have issue with the systemic failures that abound in Power determination, then argue the cause not the instrument. I have described in the past how Power determination can be upset drastically in the face of measurements performed between two mismatches (both the source and the load); but it is not the fault of the instrument in the Power determination's failure. No other instrument nor method (short of acknowledging the

indeterminacy of phase) will improve over sure failure.

"No, the meter scale comes from external calibration."

Who said it didn`t?

The scale is mass produced. In the Bird element, a resistor is selected, in some elements it is a variable resistor, called the "calibration resistor". A suitable replacement is the Helitrim 7138 mini variable.

See "Calobration and Repair for Bird Wattmeter Elements, page 48, April 1989, 73 Amateur Radio.

"That is a kindergarten concept (Multiplication is just scaling or the number of times you repeat a number in an addition column.)."

Books were written, and sold nicely, with such titles as, "I Learned All I Needed To Know In Kindergarten".

You can easily repeat a number 3.14159 times by adjusting an amplifier`s gain to that figure. A variable resistor can be made nearly continuously variable and set for any odd value.

Best regards, Richard Harrison, KB5WZI

Both of 'em actually.

> Bye bye ham radio in the US.

Don't put that in the bank. I've seen some analyses of BPL economics,
beyond dismal. Breakeven point for recovering the initial investments
is projected to be ten years out. How do you suppose Wall Street will
react to that when that black cat gets out of the bag? Power utility
mangements have to be among the worst of all possible types to
shepherd anything hi-tech comms, they're still wrapped around steam
engines.

Check out how their brethern in the oil industry, Exxon in particular
shot itself in the foot when they got the bright idea to get into the
Qyx memory typwriter business. MBA candidates are still writing case
study theses on that disaster.

If BPL is approved in the U.S. I expect it to roll over and die almost
on the spot like it has in Germany. Or it won't be allowed in the
first place per the the Japanese example and for the same reasons.

I'm not losing a bit of sleep over the prospect of BPL wiping out HF
radio.

I've been out of town since this was posted. There are a couple of details I'd like to check in some texts before responding, so I'll postpone my response until after I return home. In the meantime, I see that Ian and Tom have made contributions, both to their usual high standards. Both these gentlemen know what they're talking about, and I'm glad to have them help out.

HEllo,

I don't cliam that it is the smallest beam for what you are looking for, but
it should be considered.

Take a look at the Baby Boomer Quad by Degen Designs at www.degendesigns.com
I think it might meet your requirements.

If you have any questions, please contact me directly at
info@degendesigns.com (note: my newsgroup posting address is designed to
avoid spam and will note reach me)

>to the Bird wattmeter scale.
>
You are mistaken. You may want it to be so, but it ain't.

The Bird "power" scale is almost a pure square law, indicating power as being proportional to V-squared, where V is the voltage detected by the diode in the slug. No log function is involved.

This isn't just theory. I and another person have independently verified the Bird 43's scale law by experiment, measuring the meter current at various power levels and then determining the mathematical law of the meter scale. We even took the current measurements to the level of precision where we could see that a few of the Bird's individual scale marks weren't drawn in quite the right place relative to all the rest. We confirmed that the calibration fits the square law almost perfectly near the top end of the scale, but deviates by a few percent near the bottom end where diode's threshold voltage becomes significant.

>The Bird takes two linear voltages and adds them.

Agreed. One voltage is a sample of the voltage on the centre conductor of the Bird's internal transmission line, and the other is derived by transformer action from the current on the line. When sensing in the forward direction, these voltages are made to add in phase; then the sum is detected by the diode.

When the slug is turned around, the current sample reverses its phase but the phase of the voltage sample stays the same, so now the two subtract. With a matched load, the two voltages are arranged to be equal and opposite so you get a null in the reverse direction. That's what gives the Bird its directional properties.

>But the power scale on
>the Bird meter face is scaled logarithmically just like it is on a slide

>rule.

Sorry, that is factually incorrect, so everything you concluded from it
is incorrect too.

I suggest you look at http://www.arrowantennas.com/ specifically http://www.arrowantennas.com/146-437.html I have one of these very durable featherweights. It disassembles down to 22" long, and even has a roll-up bag available for it. Al wants an extra USD 38 for the bag, but mine fits fine in my backpack, with the boom and 2M elements in the fishing rod pocket, and the 440 elements in a zipper pocket. It's all aluminum, with elements made of Easton 1816 arrow shafts.

It weighs 20 oz in the split-boom form, 19 oz as a solid-boom - a bit over half a Kg. They're very popular with backcountry hikers, as they give good performance on 2M & 70cm in a single light package, are easy to set up and take down, and can endure a lot of abuse (think about what an arrow goes through in normal use). If you need to work crossband duplex, you'll either need a rig with two antenna connectors (that's how I work portable UO-14 with my FT-817) or get a duplexer. Al sells one that's designed to fit inside the boom, bringing the cables out the back of the handle, for USD 59 with BNC or 64 with SMA for the radio end.

I don't work for the company (though my daughter and I did get a factory tour yesterday with BARC Jr). It's just Al Lowe and his wife doing all production and shipping.

Exponent functions are exactly what logarithms are all about so I don't understand the significance of your assertion. If V(v) is the voltage proportional to the total voltage and V(i) is the voltage proportional to the total current and V(v)=V(i), are you saying that log(V^2) is not equal to 2*log(V)? I say log(V^2)=2*log(V), i.e. the square law power function is a linear function using logarithms. That's the basis of the Bird wattmeter design. I would certainly like to see a proof that log(V^2) is not equal to 2*log(V). (So would a lot of people wearing white coats. :-))

Without a "hearing" would be an apt description. I keep telling you
you should build one to actually see if it works, but you don't or
won't listen.

I now accept that all is now known about antennas
> except the really deep things that Cecil is so bravely pushing on with

> home and abroad.

Why? Are you admitting it probably doesn't work?

> Just forget about my antenna and go with the common consensus that it
> can't possibly be true since I have no credability.

I don't think your antenna will work as you have planned, but your
credibility or lack of it, has nothing to do with it. I modeled the
thing. I know how it will work. Or at least the version I tested. MK

2176. Helical Stub Antenna

Whatever it is, you may not want it. I measured the gain of a TA33JR on 20 m, and it was less than a dipole.

Source record: 111625

Hi I wish to hook up my G5RV so that the centre is on my mast and the legs go one to my chimney, and the other to my neighbours chimney. the mast from both chimney's is about 55 feet. the two chimneys are about 50 apart. It will form a V with the feeder at the mast. Will it work or is the angle to tight

Thanks in anticipation
pensal@ntlworld.com

>to the total current and V(v)=V(i),

V(v) and V(i) are *added* - vectorially, as two RF voltages connected in
series - and then the sum voltage is detected. No logs are taken and
they are not multiplied together in any other way. The detected voltage
(now DC) is squared by the meter scale law to indicate power.

You were caught in a totally incorrect statement about the meter scale
law, but you can't stop dodging. Just read again what you wrote:

>are you saying that log(V^2) is not
>equal to 2*log(V)? I say log(V^2)=2*log(V), i.e. the square law power
>function is a linear function using logarithms. That's the basis of

I fly an ultralight and recently bought a Delcom 960 transceiver. I
have used it ground based and the stock "rubber ducky" really sucks.
I receive ok, but just can't get out with it.
I am humbly asking the rec.radio.amateur.antenna braintrust to direct
me to a site (or instructions) that show how to construct a nice
antenna that I can install in my plane.
Since my plane has no aluminum skin I envision creating a groundplane
out of a piece of aluminum (24" x24"?).
What length should the antenna be? Do I attach the braid of the coax
to the ground plane?
I am very handy, but just lack the basic dimensions.
A response to joedrel@hotmail.com will be appreciated, but I will be
monitoring this group..

Any direction will be much appreciated.

Joe

2184. How a Bird works

Hi, I thought I understood this but recent discussions left me wondering.
A Bird Wattmeter provides a voltage that is proportional to the forward power minus the reflected power. This assumes the output impedance is known and constant, usually 50+-j0. Assume a Bird has a 0-10vdc meter for indication. I don't know what it is, but for discussion.
Input 100 watts into a 50 ohm load, and you get 70.7 volts, the Bird scales this to 1 volt, and you get 10% deflection on your wattmeter, or 100 watts. Input 1000 watts and you get 223.6 volts which the Bird scales to 3.16 volts, or 316 watts. 316 does not equal 1000, so the scale on the meter has to have V**2 relationship to indicate 1000 watts. So 1000 watts is 31.6% of full scale. I thought all Ham wattmeters did this. Of course it is highly dependent on the Z the wattmeter sees. Wattmeters that actually multiply V and I are another subject, it is hard to keep them in line without causing some insertion loss, is it not?

Well Cecil what ever you do do not use the word efficiency,
just use the ratio between X and Y fully stating what X is
and Y is. This way the word efficiency need not be used
for a baseless augument. I am very pleased by the way, that you are
not attempting to explain anything new but just educating the masses
on what is already known, and forgotton by the way, and re presenting
the facts of nature in a way everybody can understand that leaves no
room for argument.
If you do find something new present it in such a way that the Gurus
can respond in such a way that it is their idea or they knew it all
along but have just been to busy to write it up.
Send your paper again with the footnote that their previous response
and leadership is what you built upon and which you need further
assistance from them. It should then get printed in a couple of months
and your name printed as a foot note.
I saw a aeroplane crash data box a short time ago only to find that
is not a black "box" as previously stated. Ever thought of designing a
better black "box" to put it in and then become famous in your own
mind? The previous one made of cardboard just didn't work out when
things became all wet.

Best regards
Art
P.S. I misquoted the price of AO pro, the program actually costs $600

2186. INVERTED-L QUESTIONS

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-28 00:19:26 UTC
From: nbr <nobodyreally@hotmail.com>
Message-ID: <1bq8iv048vbmam3ern1cphe7l63o9dfm17@4ax.com>
Source record: 111630

I've put up an inverted-L, which consists of approx. 135' horizontal
leg, and approx. 70' vertical leg. I can shorten the overall length of
the antenna, but cannot lengthen it. There are about 4 ground rods
within about 10' of the base ofthe vertical element, plus about 25
square feet of chickenn wire to serve as a ground plane. I can feed
the antenna right at ground level, or can arrange to feed it up to
6-10' above ground. There is about 120' of buried coax to the shack,
which must feed this antenna. I'd like to use this inverted-L on
160-10M (will settle for 80-10M).
1) How to feed the antenna and be able to run legal limit, all bands?
Current or voltage balun? Won't a balun disspiate power and decrease
efficiency? WIll a balun at ground level increase ground losses?
2) How is the inverted-L said to be a vertically polarized antenna,
when a major portion of its radiating element is horizontal?
3) For Field Day we added another vertical leg to this antenna to make
it into a half-square, and had decent results on 40M/20M. How is the
half-square described as "two verticals in phase", when again, there
is a major part of the antenna (the so-called "phasing element") which
is horizontal?

Yes, when you add two values on a slide rule, you are accomplishing multiplication because the scales are logarithmic. When you add two values of voltage, you are multiplying them if the meter scale is properly calibrated. Log(V1^2) = Log(V1*V1) = Log(V1) + Log(V1)

> You were caught in a totally incorrect statement about the meter scale
> law, but you can't stop dodging. Just read again what you wrote:

I still don't understand why log(V1)+log(V1) doesn't equal log(V1*V2) which doesn't equal log(V1^2).

Here's an example: Let's say we have a slide rule where the distance between the '1' index and the '2' is one inch. We set the index on '2' and read the value of the product off the '2' on the other scale. All we have done is add one inch to one inch and everyone knows that is two inches. But because of the logarithmic scale we read '4' as the answer. Thus the answer to '2' times '2' is '4' even though all we did was physically add one inch to one inch. How can one inch plus one inch yield an answer of '4'? The same way one volt plus one volt can yield an answer of 200 watts.

Let's say one volt inside the Bird equals 100 volts on the transmission line and one volt inside the Bird equals 2 amps on the transmission line. When the meter measures two volts, we calibrate the Bird at 200W. When the meter measures four volts, we calibrate the Bird at 800W. That's similar to the logarithmic calibration of the slide rule. We are adding one volt to one volt but we are reading the product off the wattmeter scale.

> So "The square law power function is a linear function using logarithms".

Of course. Log(V1^2)= Log(V1)+Log(V1) does it not? Is that not a linear function? That's how slide rules work. You add logarithms to accomplish multiplication. What am I missing?

Thanks for your reply to my message, but this is not feasible. The
antenna is 120' from the shack, unblanaced transmatch in the shack.
Looking for matching network at the base of the antenna (or apex,
maybe), perhaps balun (???), but needs to be broadband so antenna can
operate multiband.

A/B comparison between the dipole broadside to Europe, and TA33 with a rotator. People who sell trapless beams make the same claim. Remember, this is the JR, with small traps, too short a boom, and element lengths that have been fudget to get a very nice 50 Ohm impedance with no matching network of any kind. (Or there is enough resistance in the traps). Front to back and front to side are also very poor.

I got comments from G and DL stations who all preferred the dipole. Receiving, the difference in favor of the dipole was huge (several S units) on an HA.

Replaced it with a full power beam on a 14 foot boom and hairpin match.

I will go so far as to say that even in the configuration that you described (original poster) it will easily outperform any $400 to $500 multiband vertical antenna that you can buy (figured on the highest average performance on the most available bands). Good enough?

>scale. I thought all Ham wattmeters did this.

That isn't how any directional wattmeter like the Bird works. There's
information at:
www.ifwtech.co.uk/g3sek/in-prac/best-of.htm#bruene

This is mostly about the Bruene bridge type (the ones with a toroid).
Those are easiest to understand, because you can see very clearly how
they take separate voltage and current samples from the line.

The original explanation came from the classic 1959 QST article by
Bruene (of the Collins company, who knows how his own bridge works) and
is backed by Walt Maxwell. I repeated it in my magazine column because
today's readers still need it... perhaps now more than ever!

My article goes on to show how exactly the same principles apply to the
Bird. Once you know about taking V and I samples, it becomes much easier
to see how the Bird's pickup loop is doing both at the same time -
taking the I sample by magnetic coupling and the V sample by capacitive
coupling.

It's also very easy to see that the V sample and the I sample are never
multiplied - only added and subtracted at RF, *before* the resulting RF
voltage goes into the detector diode.

Therefore the Bird does not directly sense RF power. As Walt confirmed
very recently, the power indication on the scale is obtained by external
calibration.

> Of course it is highly
>dependent on the Z the wattmeter sees.

Yes - but the same concepts tell you why the Bird indicates what it
does.

>Wattmeters that actually multiply V and
>I are another subject, it is hard to keep them in line without causing some
>insertion loss, is it not?

And harder still to find one - I've never seen or heard of one that does
it that way for RF.

>operate multiband.

Cecil's right - it can't be done without a matching network at the base, because the feedpoint impedance varies too much between bands.

Your antenna is about a twice-size version of mine. I have a 35ft vertical, with a 35ft horizontal section followed by a "switch" that can connect another 65ft (all dimensions approximate). It's fed through matching networks at the bottom of the vertical, against a large number of radials.

The extra length of horizontal is only used for Top Band (quarter-wavelength, low Z, needs those radials) and for 80m short-skip (half-wavelength, mostly horizontal, voltage fed so doesn't use the radials much).

With the "switch" open, it's simply a 35ft vertical, 35ft horizontal inverted-L.

Top Band: 1/8-wave, inefficient but long enough to be usable for easy QSOs.

80m: bent quarter-wave, surprisingly effective for DX, but low-Z feed and needs those radials.

40m: voltage-fed half-wave, half vertical and half horizontal - from the UK it's good for mixed European/DX working, but obviously receives the European signals even when you don't want them. High-Z feed.

Higher bands: too long - wastes power in lots of little lobes pointing in useless directions. Gets worse and worse as the frequency goes up, and even a simple dipole is better. Mostly high-Z feed.

As Cecil says, there's no choice but to feed it at the base through matching networks on most bands. Trying to feed it from the shack end through the long run of coax is a non-starter, except on the bands where it's a low-Z feed. On all the other bands the SWR is too high and the losses in the coax are crippling.

For many years I used a conventional T-match ATU out there in a waterproof box. Band-changing was possible, but a chore. Then I tried custom switchable networks, but that became too complex. At present I'm using a military auto-ATU that is 1kW rated and works like a dream.

I would certainly recommend the 35+35ft along inverted-L with an auto-ATU for any small backyard. The extra horizontal length is fine if you can get it - and the advantage of using the auto-ATU is that it can be *any* practicable length; you don't have to worry about matching any more. The only problem is that amateur auto-ATUs are limited to medium power.

Your system is twice as big as mine, so you can shift all the above comments down one band. It should go like a rocket on Top Band, but even on 40m it's getting over-long. If you have other antennas for the higher bands, think of the inverted-L only as your "low-band special" - then two or three remotely switched, pre-tuned matching networks will be all you need.

In your situation I would also consider a remote switch at the top of the vertical, to disconnect the horizontal part completely. You'll then have a very effective DX antenna for 40m. Take a look at N6RK's site, which has some information about switching out the upper sections of antennas for the bands where they are "over-tall".

Look at a J-Pole antenna. There are several websites with calculators
to design the one you want. While some people complain about their
performance J-Poles work fairly well, do not need a ground, are very
light and can be made for under a $1.

It may not be the best antenna for the job, but it will be simple
to make and may do the job you want.

Ian, G3SEK wrote:
"The detected voltage (now DC) is squared by the meter scale to indicate power."

That`s right. It only takes about 1.4X the deflection to represent 2X the power.

Cecil was saying the same with his slide rule illustration. To square a number, you multiply the logarithm of the number by 2 and take the antilogarithm of the product. The slide rule is designed to do this for you with its "engine divided scales".

Each sample taken in the Bird wattmeter, line volts and line amps, is exactly half the total sample, so one of them is really redundant to the power indication, were it not needed to cancel sensing of the unwanted direction of power transmission. The 1:1 ratio between samples is ensured by the lock Zo places on the ratio between volts and amps in the transmission line. A dynamometer has no such lock so both both volts and amps must be sampled in the absence of constant volts or constant amps.

If you are using the popular 450-Ohm window line you need only keep
the line 2ï¿½-3 inches away from you mast. Additionally twist it a bit
(about 180ï¿½ every couple of feet) and you'll be fine.

Mark,
Put the whole antenna idea aside The thing could not possibly work, my activity is a total illusion. If anything new comes along, which is highly unlikely since all is known,do you really believe it would be the likes of me to find it? A guy who never went to college, can't type or spell and has no credability. No Mike I am just an ordinary disciple of the gurus on the net
sucking up every thing that they say knowing if I differ with them I am not in conformance and thus not a part of the team.
Back to the real interesting part of radio, SWR, tuners, how far apart should my antennas be,can I make a G5RV antenna with wet string and away from antennas that are just a joke and back to reality and total conformity.
I expect to obtain more friends now and continue with my happy life.
Your friend
Art

>good luck and let me know how it turns out

This was an easy experiment...tried it and couldn't load the antenna
from the shack. Put an MFJ analyzer on it, and the impedance was all
over the place. I got the sense that while my trasnmatch might make my
transceiver happy, there was very little RF radiation going on. I've
seen the article you mention...in my case, my INV-L dimensions were
different, I am trying to operate multiband, plus 120' of buried coax
to the shack had us comparing apples to oranges.
Thanks for your comments...stay tuned!

The configuration is up to 72' of wire suspended from a cross-arm off
the top of the tower, then thru a pulley out horizontally to a tree.
The length exists because of height of tower and distance to tree. Of
course I can shorten the wire, but I always start out with "more is
better".

Your antenna sounds great. In my case I am limited on available
control lines (to power switching relays) and I want to keep this as
simple as possible (lots of ice and wind here, not to mention Murphy's
Law).
>

Good point. While I would like to be able to operate all bands, the
primary targets are 160, 80, and 40 meters. I do have an LPD for >14
MHz so the need to operate above 7Mhz is pretty minor. Guess I should
focus my energies at 1.8-7.3 Mhz.

Yes I found this out. Someone recommended direct feed (ala WH2T) but
the results were terrible.

This would be a great solution (despite the cost). I've contacted
several of the mil surplus distributers in the US and Canada, and
nobody seems to have (or know about) an ATU (manual or auto) which can
handle full legal limit. I am not familiar with the mil/commercial
matching networks....where to research?

Exactly. We used an ICOM AH2 (forerunner of current AH3/AH4) during
Field Day, running 100W, and it worked like a champ. Tune up in < 1
second, the rig was always happy, and so were the operators. This was

using the half-square, which is the INV-L I've been discussing, plus another 40' vertical leg added, making an "inverted-U" shape. Field Day conditions were terrible (QRM/QRN/poor propo) but the 1/2-square did reasonably well on 20M/40M. I would do the same arrangement in a heartbeat if I could find a device which handles 1.5KW.

>you need.

OK, so if I use 65' vertical with 100+ feet horizontal, I have a1/2 wave @ 40M vertical with a big inductor on top (the horizontal). That inductor helps the antenna greatly at 80 and 160M, but is a handicap at 7 Mhz? (Forget freqs >7 Mhz)
>
>In your situation I would also consider a remote switch at the top of
>the vertical, to disconnect the horizontal part completely. You'll then
>have a very effective DX antenna for 40m. Take a look at N6RK's site,
>which has some information about switching out the upper sections of
>antennas for the bands where they are "over-tall".

Thanks for the reference, I will check out the site. However, I again fear this is getting too complex and will be too difficult to keep in the air during our inclement weather. FWIW I am also considering a vertical 1/2 wave dipole for 40 meters (hung off the other side of the tower), so maybe I should look at this INV-L as my 160/80M wire, and the vertical dipole as my 40M skyhook.

Again, thanks for your comments!

Thanks for the recent comments on my previous post. They have been
interesting and informative.

The "antenna voodoo" is still bothering me about the theory of some of
these antennas (e.g. inverted-L, half-square, etc.). I understand that
the horizontal leg of the "L" is considered an "inductor at the top of
the vertical" element, but why not the reverse? Why is this not a
"bent horizontal" with segments which radiate both in the horizontal
and vertical planes? Why is the horizontal sengment of a 1/2-square
considered a "phasing line" and not a radiator?

Joe wrote,
"---the stock rubber ducky sucks."

A wire 1/2-wave dipole should be about 3 ft, 10 in long. Feed it across a middle insulator with coax. It should be placed about 2 ft below and in line with the wing to get a small reflection from the wing and the best signal fore and aft.

Don`t worry with a balun. Stick with coax alone. Save weight and enjoy any radiation from the feedline.

Best regards, Richard Harrison, KB5WZI

I don't think you're suggesting the horizontal component is cancelled
out??? So in truth the 1/2-square may perform DX best at low angle TOA
broadside to the two verticals, but may also have high angle lobes
from the horizontal wire (effective close-in cloud-warmer)?

Wish I knew! The one I have is made by Racal, and rated to handle 1kW into a 30-foot vertical at 2MHz. Into less challenging loads it will probably handle much more. Unfortunately the UK supply has dried up. There must surely be equivalent tuners made in the USA, but I've no idea where to look.

Trust your own eyes: the horizontal part looks like more antenna wire... and that's exactly what it is! The horizontal part will always radiate in an inverted-L configuration, so you'll get mixed vertical and horizontal polarizations.

On its own, the 65ft vertical would give you good DX performance with an overhead null on both 80 and 40, but it would be a poor antenna for short-skip. The horizontal part will fill that overhead null and provide some short-skip performance as well. Which of those features is good or bad depends on what you want the antenna to do. That's why a relay at the top of the vertical part would be a really nice addition.

On 160m you have something like a 3/8 wave in total, which should be quite a good performer.

The antennas where the horizontal part does *not* radiate significantly are the symmetrical T configurations. That is because the current flows out onto the two arms of the T in opposite directions, so the horizontally polarized radiation very nearly cancels, leaving only the vertical.

This is what I suggested but it will have to be switchable or tunable
for each band, maybe a stub for each band. There is no single fixed
network or balun that will do the job. The impedance on some bands
will be sky high and cause sky high SWRs on your coax.

I understand that Dan is coming up nd testing new version of his terrain program. I have not seen it yet.
Fine tuning the vertical arrays can use contribution from the terrain (like being on the shore with sand dunes behind), This would greatly enhance the modeling capabilities.

Keep it in the forefront :-)

Interesting, I think this could be what happened during our Field Day
ops. We worked virtually NO DX, but did decent with this antenna to
most parts of the USA. The design of the 1/2-square was "wrong" by
conventional design notes, ie the verticals were too long (approx 45'
and 65' each) and were separated by WAY too much horizontal (about
130'). If we were radiating low vertical TOA, the propagation wasn't
supporting it (or the noise level was too high). However the decent
stateside performance suggests we were warming the clouds. Our QTH was
mid-USA (Missouri) and broadside to the horizontal wire was E/W; we
worked about 40 states.

The center of the "phasing line" on a half-square is a
maximum voltage point but there is nothing to keep that
horizontal wire from radiating. At a TOA of about 65 degrees
the broadside horizontal radiation and vertical radiation of
a half-square are about equal at about -9 dBi.

Twisting tends to expose both transmission wires to the same environment.
For instance, if you ran one wire 0.5" away from sheet metal and the other
wire 1.5" away from the same metal, you would unbalance your currents
because of the metal's effect on the closest wire.

Ian, G3SEK wrote:
"Therefore the Bird does not directly sense RF power."

Problem with that statement is that to the uninitiated it makes the indication suspect. A voltmeter doesn`t measure volts directly. The ordinary voltmeter measures current scaled by a multiplier resistor. Wish you and Walt would knock off the nonsense.

A Bird senses all it has to sense and legitimately converts it to a reasonable indication of watts. The Bird can do so thanks to Ohm`s law, and that`s that.

Yes, above a TOA of about 65 degrees, the radiation is primarily
horizontally polarized and there is enough to make some NVIS
contacts on the lower bands. You get an interesting pattern if
you feed it 1/3 of the way down the horizontal wire. You get some
fairly good high angle radiation that can help fill in the nulls
in the half-square patternm i,e, the coverage doughnut gets bigger.

Gary, N4AST wrote:
"So 1000 watts is 31.6% of full scale. I thought all Ham wattmeters did that. Of course it is highly dependent on the Z the wattmeter sees."

The Bird has more than one scale on the same meter face. It`s possible to scale them any way the designer wants. With the complications of special circuits, the scale could be made linear. I for one wouldn`t want it.

31.6 is the sq. rt. of 1000, approximately. Power is proportional to the sq.of volts or amps. So, if you want to represent watts as a function of transmission line volts and, or transmission line amps, you can print the scale of a linear meter so that it advances as the sq. rt. of the current. That is, current increases to 141.4% of its previous value, and the watts indication doubles. That`s because 1.414X the volts multiplied by 1.414X the amps equals 2X the watts.

In the Bird, the impedance is always supposed to be 50 ohms. That Zo enforces a lock on the volts to amps ratio the Bird must work wiith. So, all you need to know is the volts or amps in the incident wave and you can calculate its power. Same for the reflected wave. The Bird very effectively separates the incident wave from the reflected wave by setting their samples exactly equal. In the forward wave the incident volts and amps are exactly in-phase. In the reflected wave, they are exactly out-of-phase. So, when set to measure power in the forward direction, the two equal samples, voltage and current, add. The equal reflected wave samples exactly cancel. Reverse the arrow on the Bird. That reverses the polarity of the current sample. Now the forward (incident) wave samples cancel, and the reverse (reflected) wave samples add.

Zo only permits wave propagation in which volts and amps are exactly in-phase or 180-degrees out-of-phase. The arithmetic is simple and Zo is the friend of the Bird wattmeter.

Best regards, Richard Harrison, KB5WZI

to all the people who emailed me (including those with duff return emails???)
wanting to know where the surface mount VHF/GPS antennas are, go here:
http://www.mobilemark.com/GPS_Tracking_antennas.html (SM-150/1575)

I am still looking for a similar dual band antenna that is Magnetic mounted, if
anyone can help.

Source record: 111530

Joe,
You have several options depending on the construction
of your aircraft and how much 'trouble' you want to go to.
A simple 1/4 wave element mounted to a metal structural
member of the aircraft should beat the rubber-duck to
within an inch of it's life (only added weight would be the
antenna element and feed line, no 'plate').
The 'best' place to mount an antenna on an aircraft is
also the least convenient, usually. Guess that depends on
where the motor is (motors = RF noise makers). The center
of the aircraft is probably the 'best' mounting place since
it would give you a more or less omnidirectional radiation
pattern. Directional radiation patterns are NOT desirable
on an aircraft (com or nav)!
Good luck, and let us know what happens...
'Doc

I do not exactly understand what you mean. When refering to the
antenna input imedance value(s). These are output values and depend on
the structure which is computed/optimized.
When refering to lumped loads, wire- or other distributed loading,
these can be configured as variables to optimize.

> Also, how many variables do you have available

Whit the latest version (5.3.3) this number is not limited. In
'real-life' however when using a very larege amount of variables to
optimization process will ttake a long time....

> together with max number of pulses used ?

Mininec is using pulses. Nec-2 is uses segments. However they have
almost the same meaning. For none windows-XP systems you can use a max
of 11.000 segments when using windows-XP, you are by default limited
to 5000 segments. However I can deliver exe's with more segments on
request for free.

Greg,
Aside from the electrical affects of twisting the
twin lead you also have the benefit of making it less
affected by wind. It 'flops' around less than if it
wasn't twisted. Ever noticed how the 'tape' advertising
thingys are really affected by wind if they are ~not~
twisted?

Cecil, W5DXP wrote:
"Are there any locations up and down the line and/or any value of load that will cause the Bird wattmeter not to read 100 watts forward power?"

Cecil has eliminated a re-reflection with his circulator at the generator.

Therefore, the Bird, being insensitive to power traveling in the opposite direction to that sensed, should read 100 watts forward power at any location in the line.

There must be enough transmission line to enforce Zo. The width of the Bird case is likely insufficient line length.

Another caveat is that the Bird elements were designed to balance using a 50-ohm load on the line, but were intended and have proved workable on mismatched lines.

Another frequent question is, "How about a large reactance termination?" Not to worry, again, given sufficient line. Terman and other authorities report that this reactance only displaces SWR patterns on a line. That is logical considering lengths of transmission lines as reactances themselves. So as Cecil would likely be quick to point out, adding a reactance is tantamount to adding a length of transmission line, and vice versa.

SWR should have little effect on power determination with the Bird wattmeter which is performed as : Forward power minus reflected power, period! With the circulator, disposition of all power is clear. The forward power must contain all load and reflected power which only makes one round-trip.

Best regards, Richard Harrison, KB5WZI

Yep, and as I said, (baring nonlinearities) the sum of the voltage proportional
to the total voltage and the voltage proportional to the total current will
be constant as long as the 100W from the signal generator remains constant,
no matter what the load or SWR or where the Bird wattmeter is located on
a lossless line. It's easy to prove mathematically.

Let's approach it a little differently. Assume a signal generator equipped with a circulator load driving a lossless 50 ohm feedline. The load is variable.

100W SGCL----50 ohm lossless coax--------variable load

Are there any locations up and down the line and/or any value of load that will cause the Bird wattmeter not to read 100 watts forward power? In the above example, I can show that the two voltages that get added inside the Bird always yield a constant value of voltage, i.e. and therefore a constant power indication.

Richard, That is exactly what I was trying to say, one can measure the
power absorbed by a known resistive load by sampling V or I, rectify, scale and
display on a log scale meter, or is it square law? Whichever one it is, it
ain't linear.

Maybe that's because your understanding isn't in accordance with the rest of the industry. :-)

I retired 10 years ago and for a decade prior to that I maintained a series of UHF repeaters on 456 Mhz - all of which used SO239/PL259 antenna interfaces, all designed and built at the General Electric factory in Lynchburg, Virginia. Evidently they didn't consider the connectors "useless" at that frequency, and after years of dealing with them, neither do I. There was never a single instance where I saw a single problem with them.

What are you talking about ? There are no "circulators" in a Bird!

What?

The Bird merely samples V and I at a single point on the line
and it's internal analog computation circuitry computes power
from those two measurements of voltages. B= V - RI the
computed reflected voltange and A = V + RI
the computed incident voltage, what's the big deal?

> > characteristic impedance)...
> >
> >

Exactly. Close impedance matching is one of the most overrated goals in

radio, in my view and after nearly 50 years of experience.
The exception (there seems to always be one) being in cases where it's
vital to preserve every last milliwatt or fractional microvolt of RF.

Don't believe it? Just replace your RG8 or whatever with 72 ohm RG9
or almost any other other coax, of almost any impedance. Sure, you can
measure the difference at the far end if you work at it hard enough. But
does it really matter? Almost always the answer is a resounding NO!

And "brief" impedance discontinuities even at frequencies 'way up there

seem about as inconsequential under most conditions.
Once I needed to hook up a small dish sattelite TV system, which
operates above 2 GHZ as I recall, to use for a few weeks in temporary
quarters. The only opening available to the outside was a small drain
slot in
an aluminum window frame. So I simply used a foot of small speaker
twinlead to transition through the slot and resumed outside with the
RG6, on to the dish.
(Of course I was very careful to preserve cable polarity since DC
operating voltage for the LNB at the dish travels on the cable).
As far as I could determine, the system was not affected in any way.
Even the
'signal meter' reading on the TV screen was not discernably lower.

Yoiu've got to get the tip VERY HOT before applying it to the connector for it
to work right, then as has been said already, don't stay too long or you'll
melt the inner conductor of the coax, and get to start the job all over again.

> the likes of me to find it?

If you really believe all is known about antennas, I doubt you will
find it. You'll never get anywhere with that restrictive mindset.

A guy who never went to college, can't
> type or spell and has no credability.

I don't think anyone really cares. I'm sure some would wish you would
use a spell checker though...I didn't go to college either. Why are
they not jumping my ass on a daily basis? It's quite simple really. I
don't randomly grasp at straws trying to explain something that I'm
not really sure how it works. This is what you are doing. If I have
this problem, I don't say anything usually.

Just curious....Why on earth is it so important that you convince us
this antenna works, is the cat's ass, or other assorted descriptions?
If it were me, I would have built the damn thing years ago. I would
KNOW if it worked or not. No guesses, grasping, etc needed. Then all I
would have to do is try to explain how it works, which to the average
ham on the street, isn't probably that important. If it works, it
works. That all many care to know.

No Mike

Who's Mike? Is he that guy that sits by the pay phone at the local
stop and rob?
He's there every day nearly. Usually tries to hit me up for money...

I am just an ordinary

Dang....Kind of depressing results...I would have thought the small
beam would still slightly win the race. I use a A4S here when I
actually use a beam. I got it free, so the price was right. It's
fairly decent actually, but I don't consider it a small beam. It's
full sized for all practical purposes. 18 ft boom, and a 32 ft
reflector. It has "nearly" full size performance on 20m. Also good on
10m with it's better spaced reflector than the smaller A3. The A3 is
not bad though. It's about a 27 ft reflector if I remember right. We
have compared the A4 to the A3 at field day. The A3 wasn't too bad
considering it's slightly smaller size. Both the A4 and the A3 use a
spacing design that gives a 50 ohm feedpoint. You only need a 1:1
balun or a choke. I use the coax choke.. MK

Nope!

The "thing" that separates the incident voltage wave from the reflected voltage wave
is called a directional coupler [actually a bridge circuit].

A directional coupler is *NOT* a circulator. One can make a directional coupler from
a circulator but not vice versa.

But, one can make a circulator from *three* or more directional couplers arranged in a circle!

I'll post schematic circuits for "electronic" directional couplers and circulators on
alt.binaries.electronics.schematics if you wish.

Many useful inventions have come from people that on the surface, you would think are surely dumbasses in their fields due to lack of training. I can think of many right off the top of my head. I don't think Bill Lear had too much school and training, but he seemed to do ok as one example. I think he invented the 8 track, along with a few other aviation related patents. "I think anyway"..
Not to mention cobbling together the jet airplane which is quite common at airports these days. So this "poor dumb ole Art" crap is not going to fly far with me. If you feel the antenna would work, I think you should build it. I would ignore everything everyone says. BUT! I wouldn't presume to flog others for their lack of "vision", just because something you don't even use or seemd to have built in real life is not readily accepted as practical. If you think it's a great idea, use it. The end performance will tell the true story.
As an example, note the "EH" guy. Personally, I think he's on a misguided turd hunt, but at least he's got the nads to actually build the crazy looking things. And this eventually lets others compare them to tell the true story. Unfortunately, his antenna seems to be primarily a feedline hanging device. It supports the feedline, which is the "real" antenna and does the bulk of the radiating. I think a pully or other hanging device would be about as efficient overall. :/

No, there's a circulator in the source to keep the forward power
from changing with SWR.

> the computed incident voltage, what's the big deal?

There's no big deal at all, Peter. But did you realize that the
the voltage proportional to the total voltage vectorially added
to the voltage proportional to the total current is a constant
as long as constant forward power and constant reflected power
is maintained no matter what phase exists between the forward
and reflected waves? Mull that one over for a bit.

Mark,

I bought the Hygain TH3Mk4, which is about the size of the A3. It is a WHOLE lot better than the Junior. I think this guy is looking for stuff that is smaller yet (than the 33JR).

Another indicator is that if the antenna won't take full power, it has lossy traps. I finally burned out a trap on the 33JR by running a KW into it. The comparison to the dipole was done before I burned out the trap - somebody once asked me...

I don't know how much power you are running, but your A3 and a linear would give you more ERP than any antenna improvement you could make. I had spent about 1/2 hour trying to work Ducie Island barefoot. Finally gave up and turned on the linear; the guy came back to me on my second call!

This isn't tough. You have the makings of a fine 160-10 meter antenna.

Step 1 - add wire to run the vertical leg back up toward the top to make it a total of 135 feet long. (linear loading)

Step 2 - feed it at the top center with 450 ohm ladder line (no radials or ground plane needed now) Run the ladder line away at an angle to be equidistant from the legs of the antenna and put a twist in the line about once every two feet.

Step 3 - run the ladder line back to a 1:1 current balun as close to the shack as you can (Centaur had some nice big ones)

Step 4 - coax to the tuner in the shack. You may not even need the tuner on 160.

Step 5 - enjoy. I do.

Yeah but..... Remember Iridium?? Not 'zactly a gallopin' bizzness plan but
they got the spectrum and the $$$ backing to toss up something like $22bil
worth of hardware into the sky before reality struck. All very "high tech" and thus highly
desirable to the
regulators who get stars in their eyes and froth at the mouth at the very mention of the
name Carl
Stevenson...And if Bill Gates

and a couple other Guru level geeks climb on board this train's REALLY rollin'......

I sure wouldn't ignore the threat of BPL just because it stinks from almost every viewpoint except that it's
highly desireable as a high tech solution to
a percieved-but-not-necessarily-existant problem. Commisar Powell really
thinks it's THE solution to getting everyone in the world wired.....That alone is trumps tons of logic.

Heh, heh... Actually the closest thing to a "two port circulator" is an
"ideal
transformer" it has the same scattering matrix as a two port circulator.

BTW... here's an interesting rhetorical question that is often posed
in texts on the scattering matrix.

How many different kinds of three port circulators are there?

Hi Tom,

Well I have little to fear of that from this group.

I just saw Gilbert and Sullivan's "The Gondoliers" last Saturday night, visited the new Opera house the week before (they were setting up for "Parsival") and have been to more than a few Opera fund drives in the past year (full dress dinners). Then there were several Balls, lectures (National Geographic), the Bavarian Symphony (front row, third balcony - nie wieder!), "42nd Street" and as the King of Siam would say: "et cetera, et cetera, et cetera." Hardly describes my calendar for the year.

Back when I was in the film society, we had a hook-up program with the Opera's Ring Cycle and showed Fritz Lang's "Die Nibelungen." To most who even recognize either, that wouldn't be so remarkable until you

realize that this was a silent movie. There were quite a number of "silent" Operas done in the 20's.

Well, Tï¿½ was a hoot (and kept us cool to boot). But #@!$8.50 is getting too steep for a shorter sequel. The story is rather derivative from Tï¿½ (the liquid metal pursuer, even if a girl, is getting a bit thin). There seems to be a new logic in showing movies (matches some of the posting tactics I've seen here), if the plot is wobbly, turn up the volume.

Myself, I tend to consider it capacitance rather than inductance. IE:
one leg of a top hat.

Why is this not a
> "bent horizontal" with segments which radiate both in the horizontal
> and vertical planes?

In a way it is, but the vertical radiation overshadows the horizontal
when using a 1/4 wave long inv L. Maximum current is at the base if

you are feeding it at the base. The thing with your antenna is it's longer than a 1/4 wave on even 160 meters. So you will have more radiation from the horizontal wire than you would a shorter antenna. But on some bands, this may not be a bad thing. To run on 160m with power, it's fairly simple. Use a big variable cap in series at the base to tune out the reactance. The match should be usable. And the antenna will work well for mid range use. Better close in than the 1/4 wave L. The max current point is well up the vertical part from the base, and ground losses are reduced. But it might not be as simple on the other bands. You almost need a tuner at the base. A simple L network should do the job. It would be much simpler for all band use if you had a 135 ft center fed dipole fed with ladder line to a tuner in the shack. The overall performance on most bands would be better. If your run of coax to the antenna were real short, and you used good fat coax, you could tune the L with a good tuner at the shack and have a usable signal. But I think you said you had 120 ft. Thats a bit long for very high SWR use. And being it's buried, the expected likely common mode currents that could be usefully radiated, will be wasted heating earthworms...:/ MK

Hi Richard,
If I'm permitted to add a little trivia, Jean and I were in St. Petersburg earlier this month, where we saw the Russian Kirov Ballet performing "Gisele' in the Kirov theatre. We also saw the house where Tchaikovsky lived during his later composing days.

Mark:

Thanks for your explanation (which even I was able to comprehend).
When I get into these antenna mysteries, the thing for me to remember
is to focus on where the likely voltage and current points are on the
element(s), and from there I have a better chance of prediciting the
characteristics of the antenna at a given frequency. Otherwise it's
pure voodoo. (I need to tattoo a couple graphs on my hand.)

As to this particular project, I've received several interesting
suggestions, some modifying the shape/size, some adding a tuner at the
base. I'm probably gonna try both. I have a line on an extra tuner,
which I'm gonna try to weatherproof and install (single band) at the
base of the antenna. From there, maybe do some wire pruning.

Again, thanks for your comments.

You could probably learn a lot by using a modeling program like EZNEC,
which is available in a free demo version at http://www.eznec.com

Mark,
A couple of correction before I completely move away from my antenna
Yes I did not got to University, nor did I have a normal schooling in
my childhood since the London was undergoing changes forced upon it by
a man named Hitler
However I do believe that I have gained an education of sorts since I
managed to
meet all academic requirements as a P.E. I came to the States because
of offers that I received (expenses paid)My family sold up after three
months and followed me when it was realised that I ccould not last for
ever on fast food.
Since I workrd for G.E. as a Senior engineer upto retirement I now
lead a comfortable life. The patents that I wrote up on antennas
reflectes my inexperience with the subject but the present write up
should be more readable
when it is finally accepted by the P.T.O. As far as actually making my
antennas
it would be foolhardy not to, including double checking with computor
analysis together with academic review from first principles. All of
the above was done as a hobby to suit myself only as a 'lifeline'
activity after a serious illness. Enough said... my present project is
a 'micky' mouse tuner.
Best Regards
Art

Source record: 111577

Seems like a lot of hams with limited resources are still compelled
to operate on many bands with just a long wire and a tuner.
The wire is inexpensive but the tuners are not. Thus my present
project.
I was given a Palomar enginnering balun with 5 female connenection
which by selection can match a antenna in steps from 5 ohms to over
450 ohms
in a series of steps. I am presently rigging it up so that all
steps can be switched thru remotely by a single motor. The switching
arrangement
is the main challenge since inexpensive means simple.
Now I have not measured losses of the balun before hand because the
switching
challenge is what is driving me.
Anybody have any thoughts about what I should expect from this
balun other than knowing that it is not a tuner as is generally known
since
it does not have the ability to obtain the priceless 1:1 condition
that so many desire?
Regards
Art

Source record: 111579

I have a problem with my MFJ-986

The two 1N34E of the control power and the system of TOS meter have qrt ....two time. I don't know the reason but it is not about too big power or some thing like that....Not in use or in qso. I think it is with statics (when there is a storm, or snow..or ??) I have also put 2X1N4148 and also go qrt...

I have put two 1N4001 but all the measures of power or swr are wrong... I cannot tune the god power. But they have no qrt for the moment !!

Is there anybody who have the same problem ?? And what kind of pin can I put in place of the 1N34E ?? to find again the same characteristic of the MFJ 986 at the beginning ?? and be much powerful than the 1N34E ??

Thanks for your help and excuse me for bad english. I hope that you can understand me !

You know, I've been meaning to do exactly that. A few years ago tried
a free demo (might have been early version of EZNEC?) and was scared
away from it because I found it extremely difficult to input the
antenna data....a simple dipole in free space was no big deal, but the
oddball antennas I like to experiment with (goofy lengths, bends and
angles,(in real world environment...near tower, metal barn etc.!) were
practically impossible to input.Garbage in, garbage out. Will give it
another try.

2289. Variable stub

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-29 17:07:37 UTC
From: Alfred Lorona <w6wqc@dslextreme.com>
Message-ID: <bg69l2$kohm3$1@ID-49117.news.uni-berlin.de>
Source record: 111583

For us inner city people who would like to operate the 160 meter cw contest, a 160 meter dipole is out of the question. Even an 80 meter wire is not possible.

Modeling a 14 gauge copper 68 foot dipole on 2 Mhz at 35 feet over real ground shows a feedpoint impedance of 7-j2700 ohms. This translates to a 3.11 dB total loss in a 50 foot long low-loss open wire feedline. If the 2700 ohm reactance can be eliminated, the total line loss becomes a more much acceptable .25 dB. This can be accomplished with a stub but that is good at only one frequency.

If the antenna copper loss is excluded in the simulation, Z is 2.8-j2700 ohms and the feedline loss is still less than 1 dB after reactance cancellation.

Use two parallel feedlines. Clip a 60 foot line onto the dipole. Connect a 30 microhenry high Q variable or roller coil at the station end and adjust it for +j2700 ohms at the antenna end. This acts as a variable stub. Voila! the reactance is cancelled out.

Notwithstanding the lowered radiating efficiency of a short dipole or the match loss introduced by the antenna tuner, at least the line loss is minimized to an acceptable level.

Sounds like the 1N34 reverse voltage spec may be being violated. Maybe
paralleling the 1N34 with a power Zener diode would help? The Zener
voltage should be a little less than the 1N34's reverse voltage rating.

Source record: 111586

I see that most of your questions about inverted L antennas have been answered.

The questions you asked (quoted below) illustrate the danger of trying to oversimplify antenna operation. For example, the problem with the "inductor at the top of the vertical" is simply that the horizontal leg isn't just an "inductor at the top of the vertical". If you consider it one, you end up with dilemmas like you've encountered. Likewise, dividing wires into two separate and distinct classes of "phasing lines" and "radiators" gives you no room for wires which do both simultaneously (let alone deal with "phasing lines" whose phase shift doesn't equal the electrical length of the line, which often happens).

You'll have to develop a more basic understanding of antenna operation, and avoid trying to pigeonhole antenna characteristics into a convenient handful of categories, if you're ever to have antennas make sense and cease being "voodoo". The EZNEC demo is a way many people have found to help learn what's going on. If you do download the demo, be sure to go through the "Test Drive" tutorial to get started. If you don't find EZNEC to be your cup of tea, there are now a number of free antenna analysis programs available, and you'll probably find one that's to your liking.

You're going to a lot of unnecessary trouble and expense for receiving
only.
The ham radio transmitting loops are way larger and heavier than your
needs
require, and more difficult and troublesome to tune.
Do a google search on recieving loops and go from there.

Dick

2294. Re: Variable stub

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-29 18:22:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <videqb5o5iga7@corp.supernews.com>
Source record: 111588

There are a couple of interesting things this analysis reveals.

The first is that wire loss is reducing the antenna efficiency to 2.8/7 = 40%, or a loss of just about 4 dB. So making it out of a larger diameter wire, like the shield of a piece of coax (with the coax intact so that the shield stays full size), or a number of parallel wires, would be a useful improvement if physically practical.

Another thing is the importance of the loading inductor or stub Q. If the overall Q is, say, 100, then the inductor/stub will introduce 27 ohms of additional loss resistance. This would reduce the antenna gain (due to efficiency reduction) by nearly another 7 dB (assuming an initial 7 ohm feedpoint impedance). If the overall Q is 400, it'll introduce 6.75 ohms of resistance, for about 3 dB extra loss. So it pays to make the stub/inductor Q as high as possible. Some antenna manufacturers would have us believe that stubs are lossless, or at least low loss. They're not -- it's not hard at all to make an inductor whose Q is considerably better than a stub. Open wire stub loss can be determined by modeling as wires, with and without wire loss. Of course, if the stub is made from twinlead or window line, its loss will increase considerably when wet.

The 1N34s are basically Germanium devices with low forward voltages,
typically less than 0.3 volts. The 1N4148 and 1N4001 are silicon devices
with forward voltages typically to 0.7 volts.

You should be tracing the cause of the over voltage or overcurrent on
the 1N34s. Something else is wrong in the tuner/VSWR meter. Possibly a
shorted capacitor or shorted resistor in the VSWR sense circuit.

I should have noted that the signal traveling on the coax is somewhat lower
than 2 GHz since it is downconverted at the dish to a "block" band of
frequencies
that the set-top receiver tunes. I'm not sure what the block-down band is
for the
small-dish systems, some of the the earlier large dish C band systems used a

band around 800 MHz. But the point remains.

>Don't know if anyone has considered this, but if the BPL lines are going to
>radiate intereference, would it not stand to reason that the lines would be
>(not by choice) accepting outside RFI sources???

Correct... and there have been some very pithy statements concerning
this issue submitted to the FCC.

A few I've seen (from the ARRL and others):

- The FCC recently turned down the request for an amateur very-low-
frequency band, on the basis of concerns voiced by the power
companies. The power companies asserted that their existing
power-line-control equipment (which uses VLF signals on the lines)
would not be able to tolerate even the level of EMI induced by an
amateur transmitter running just a few watts of power, on
frequencies where neither the amateur antennas or the power lines
are likely to be acting as efficient radiators/acceptors.

Now, BPL is being proposed... and its proponents are asserting (or
assuming) that BPL can operate effectively even in the presence of
much higher HF interference levels, generated by amateur
transmitters running at legal-maximum power, on frequencies where
the antennas and power lines will be much more efficient.

As the ARRL comment put it, "You can't have it both ways."

- Voltage levels induced by amateur-radio and other licensed
transmitters will likely be high enough to saturate the RF front
end circuitry, and the digitzers, used in BPL modems built to
typical consumer-electronics standards. This could very easily
result in loss of BPL connectivity over a fairly significant area
around each licensed transmitter station, whenever the transmitter
keyed up.

- Getting the BPL signals through, or around, the existing low-pass
filtration created by powerline transformers will require
installing high-pass bypass circuitry. This circuitry will
necessarily couple RF noise on the lines just as efficiently as BPL
signals, and will allow RF noise (e.g. triac switching noise, motor
commutator noise, etc.) to travel on the lines quite a bit further
than it does today.

Hi Tom,

You've just given me the opening to rub it in a little. We took a three-week
N European Cruise from Dover to LeHavre, Oslo, Copenhagen, Rostock, Gdansk,
Tallinn, St. Petersburg, Helsinki, Stockholm and back to London. One of the
best cruises we've had.

Had a lot of fun with the GPS. It still worked while in Eastern Longitudes.
I got Ian's phone number from Roy, but any time I was available to call him
was an inappropriate time to call him, so I missed him. Roy emailed Reg to
have him email me his address, and I sent him two emails asking for it, but
he never answered. Was hoping to be able to meet them both while in England,
but better luck next time. I hope you're drooling, Tom.

Some comments in addition to Roy's...

First, if you're cancelling out the reactance by _paralleling_ +j2700 ohms, then the net impedance will be very high, NOT 7 ohms. My calculator says (7-j2700)||(0+j2700) is (1041428+j2700). You'll be wanting to put that +j2700 in series to see 7 ohms net. It's likely to upset any balance you were trying to maintain...

Next, if you feed a very low impedance such as 7 ohms with a line much less than a quarter wave long, you'll be better off to use a line with large conductors, even if it's low impdance. In fact, it might well be to your advantage to use 25-ohm coax, or balanced line made from wide, flat wires. That's because in such a short line, there will high currents everywhere along the line. Open-wire line with small conductors will have MORE loss than coax with larger conductors in this case.

Finally, I agree strongly with Roy about the loss in the tuned stub. Let's look at some numbers. I believe that Reg has a program that will tell you what to really expect at the antenna end of that "tuned stub". In any event, a 60-foot line will be close to 1/8 wave long, and cause a very significant impedance transformation. Looks like the 60 feet of 300-ohm tuned-stub line, if it has only 0.1dB matched-line-loss, will present a terrible 285+j2700 ohms at the antenna end, if you put a pure +j278 ohms at the "shack" end of it. (If you use different net electrical length and/or frequency than I did, expect small variations in the numbers.) Note how absolutely AWFUL that makes the antenna! If you can drop the stub line's macthed-line-loss to 0.01dB (good luck!), you still end up with 28 ohms in series with your desired +j2700 at the antenna end. That's still ten times the antenna's feedpoint radiation resistance.

I'd say you'll be much better off to put a fixed loading coil in the antenna (probably half-way out in each leg), and just use the best line you can to bring the feedpoint back to the shack, and tune it there, assuming you don't want to have a remote controlled antenna tuner.

Cheers,
Tom

>which I'm gonna try to weatherproof and install (single band)

Dan, I homebrewed a remote controlled tuner that would work with your antenna, and you could change bands without ever leaving the shack. It uses a motor driven roller inductor and variable capacitor in an "L" network. I also have a relay switching scheme to reconfigure the "L" network. With this tuner at the base of a vertical or inv. L you can match a wide range of impedances. The L and C in this tuner are rated at legal limit.
Obviously the only thing standing in the way of you using something like this is obtaining the parts and building it. The inductor is surplus, about 30 uH. MFJ sells one that they use in their 1 kw tuner, around $65. The capacitor is a Ten Tec 500pf variable cap. kit, around $45. The drive motors came out of a kids battery operated car, 12vdc around .5 to 1 revs/sec that can be changed with the supply voltage. The hard part is coupling the motors to the L and C. The control cable is 100' of 8 cond.#20 shielded industrial control cable, about $45. Forward and reversing was done with relay logic.
This was not a weekend project, but it wasn't that bad either. If you want some more details, email.

Kind of what I was thinking, but I thought of putting some reactance in
SERIES to make the real part of the PARALLEL impedance around 50 ohms. Then
tune with more parallel reactance. There might be a problem with the Q
getting too high, though.

To answer your question, to tune the antenna to the band you are listening to, just play with the knobs until the reception is as good a you can get it. It is no more critical than that. Dick is right. The mfj loop, while it will work just fine, is a lot heavier and more expensive than you need. Home made loops will perform at least as well and, since they don't have to handle several hundred watts of power, can be made of lighter, more economical materials. Try this link. This is only one of many.

One of the technologies we have ignored in the BPL discussion is the use of coherent detection in the BPL circuitry. It provides very high common mode rejection. For example, high rejection to amateur and commercial HF/VHF transmissions, and high signal to noise integrity on the desired frequencies.

Coherent detection can very easily pull a signal out from under the noise level. For example, I have used systems where the signal can be 20 dB below the noise and still be recovered.

It may just be possible that interference TO the BPL system will not be severe, but interference FROM the BPL system ... well that has been discussed.

My understanding is that the BPL systems being proposed, use various spread-spectrum techniques - I believe they're based on discrete-multitone / orthogonal frequency division multiplexing modulations, similar to what's used for most ADSL systems these days. There won't be a single carrier frequency... there will be dozens or hundreds in use in any given transmission.

That's how they can get a lot of bandwidth over the wires, provide some resistance to narrow-band interference, and still manage to keep the radiated energy in any given band-slice to within the FCC emissions limits.

>Coherent detection can very easily pull a signal out from under the

That works nicely with narrowband signals, and at low data rates.

Doesn't seem to me that it will work at all well with wideband multi-carrier systems such as DMT, operating at high data rates.

Also, achieving high common-mode rejection is nice, but since power lines are a long way from being electrically-balanced at HF/VHF frequencies, there's going to be a whole howling lot of differential-mode signal on the lines any time a licensed transmitter keys up in the neighborhood.

Also, getting good common-mode rejection (for coherent detection or otherwise) requires that you have adequate dynamic range and resolution in your front-end electronics... if the interference saturates the receiver chain at any point _before_ the common-mode portion of the signal is eliminated, you're screwed. That's one of the problems one commenter discussed on the FCC page.

Art, are you sure you have a balun? Your description sounds like a tapped r-f transformer.

A balun, of course, is completely different from a transformer in that it is a "transmission line transformer" which is made of short transmission line sections instead of "windings."

If a balun is made with line sections of Zo, then the load must be an appropriate multiple of Zo and purely resistive for the balun to function properly.

Usually it is best to let a balun do the current steering and keep the outer braid of the coax "clean" and do the impedance matching elsewhere, as in a tuner.

Just a thought . . .

Well, doesn't have to be, but if you are using coax , it should be to reduce feedline losses. Would be a concern the higher in freq you go. I'd never run a severe mismatch on VHF or higher unless the line was a low loss ladder line. But I rarely use ladder line on VHF... I do run mismatches on HF at times, usually on the warc bands using my 80/40/20 parallel dipoles fed with the tuner, but I am taking a hit with some feedline loss. Good ladder line is low enough loss, even with a large mismatch, you don't really have to be matched. 85% of the antennas I use are coax fed, so it's more important to me than it might be to others using ladder lines. MK

I'd rather wind a coil, "oatmeal tube carton"? and find a good
variable cap, and make a simple L network to feed a random wire. I'd
rather not use an apple to do a job that an orange should rightfully
have. :/ MK

>some more details, email.

A few more thoughts, in case they're useful to Dan or anyone else:

* It's sometimes possible to make an automatic two-band network. For
example, the same 33ft end-fed vertical can be matched as both a
half-wave on 20m *and* a quarter-wave on 40m, with one network and no
switching. The same goes for a 66-footer (vertical or inverted L) on
40/20, or a 130-footer on 160/80.

* Remember that the remote network doesn't have to give a perfect match.
If the SWR on the coax is below about 3, the extra losses won't be
significant (except in extreme cases) and you can always do the final
"flattening" to 50R in the shack.

* Instead of remote rotary switches, consider latching vacuum relays
which don't require power to hold them closed. There are surplus vac
relays at very reasonable prices at:
http://www.mgs4u.com/#president

* You can reduce the number of control lines by sending cunning
combinations of positive and negative DC, AC out from the control box,
and using steering/blocking/rectifying diodes at the remote end.

> Could a parallel reactance change the series impedance to 50-jX
> and then +jX series reactance be added?

Yes, or as Tam suggests. For your network, +j1967 in parallel will
get you about 50+j7241, and small series capacitance will tune that
reactance out. But before you try it, put in a practical loss number
for the shunt inductance; it will change things significantly.
Re-adjusting for a coil Q of 100 instead of infinite changes the
series capacitance from 12pF to about 30pF (at 1.8MHz). Also, tuning
will be quite sharp and it may not be easy to find the proper match if
you have only an SWR bridge. Then the sharply-tuned network is at the
antenna, and not easily accessible.

I'd suggest comparison of this problem with what you get with loading
coils in the antenna elements, about half-way out.

Cheers,
Tom

Well, yes, speed (meters per second) is related to distance. Force (Newtons) is related to work (Newton-meters). But speed isn't distance, and force isn't work. The mass of the Earth is related to its orbital velocity, and mass certainly isn't velocity. Worse yet, the impedance of free space isn't a measure of the same thing as the characteristic impedance of a transmission line. What I'm trying to illustrate is that because two things are related doesn't make them the same thing, or necessarily even close to the same thing.
>

Yes, that relates voltage and electric field. Don't overlook the bit about the path, though.

> Say PD = E^2/Z0 = H^2 * Z0. If you say the Power Density =

> impedance of free space will a resistive impedance or load.

No, all you're doing is showing that they have the same dimensions. It just doesn't seem to be sinking in that having the same dimensions doesn't make two quantities the same thing. I've tried with the example of torque and work, but that doesn't seem to be having any effect. Maybe someone else can present some other examples, and maybe, just maybe,

with enough examples the concept will sink in.

> Roy, what do you think 1uV/meter really means in terms of how you
> measure it? I mean, under what conditions must you have to measure
> this 1uV/meter?

As I mentioned before, it's usually measured with a short probe.

But electric field is actually defined in terms of the force on a charge. You'll find an explanation in any basic physics text, as well as many places on the Web. In Weidner and Sells, _Elementary Classical Physics_, Vol. 2, the authors define electric field E as F/q, or the force that would be exerted on a (sufficiently small) charge at the point at which the field is being measured. They explain that the units of electric field are newtons per coulomb which, it turns out, has the same dimensions as volts per meter. So to your argument that electric field is "related" to voltage, it's equally related to distance, force, and charge. You can, in fact, find a bundle of other equivalent products and quotients of units that are equivalent.
>

> radiator ("the potential of a point in space is the work required to
> move to that point a unit positive charge, starting an infinite
> distance away...potential increases as one positive charge is moved
> closer to another positive charge" - Skilling).

Here we are again. Potential and voltage have the same dimensions, but aren't necessarily equal. And as far as I can tell, "voltage potential" is meaningless. To quote from Holt, _Electromagnetic Fields and Waves_, "When the electromagnetic fields are static, as we shall see, the voltage drop along a path equals the potential drop between the end points of the path. Furthermore, these quantities [voltage and electric potential] are also equal in *idealized* electric circuit diagrams, and they are approximately equal in physical circuits, provided voltmeter leads do not encircle appreciable time-changing magnetic flux." Pay particular attention to the last qualification. When a time-changing magnetic field is present, the voltage drop between two points depends on the path taken, while the potential drop is simply the difference in potential between the two points. So the voltage between two points in an electromagnetic field can be just about anything you'd like it to be.

Actually, "far field" is often defined as a distance of 2L^2/lambda,
where L is the length of the antenna and lambda the wavelength, although
the authors generally admit to its being quite arbitrary (cf. Kraus,
Antennas). In Jordan and Balmain's _Electromagnetic Waves and
Radiating Systems_, they explain that the far field approximation is
valid at distances large compared to a wavelength and to the largest
dimension of the source. This is a somewhat conservative definition.
True far field wave characteristics occur only at an infinite distance
from a source, and how close you can come and still have the
characteristics be close enough to true far field depends on the
application as well as the antenna. So there's no strict definition. For
a lot of antennas and applications, field characteristics are close
enough to being far field at a distance of well under a wavelength. For
others, many wavelengths are required. Ian posted a good summary of
salient far field characteristics several days ago.

RF isn't any more nebulous than any other aspect of engineering.
Engineering is a practical discipline, so compromises and trade-offs are
universally necessary. Because we deal with real, physical objects and
are stuck with real measurements, the absolute precision of mathematics
and the pure sciences is never attainable. This is as true for using an
I-beam as it is for RF design. But the principles of RF are at least as
well known as the properties of I-beams. In fact, a good argument could
be made that RF is better known.

Subject to restrictions and poor location, I can't install any antenna.
My window has an aluminium frame.
I considered to use it as a loop, but it is inherently shorted.
How would you feed that ?
Freq : FM BC band.
Window : abt 0.90 * 1.60 (metres)
Thanks by advance.

Wes Hayward, W7ZOI, published either a QST article or a Technical Correspondence piece about doing this, many (10? 15?) years ago. A search of the QST CDs should turn it up. If I recall correctly, he concluded that either a two-band solution could always be found, or that he wasn't able to find a combination that he couldn't find a two-band solution for.

Just by observing this newsgroup, though, it seems like very few hams are any longer interested in matching an antenna to a feedline, preferring to buy ladder line and a tuner instead.

My antenna setup is nothing but a random wire going from a tree/ tuner/ rig in the basement about 60-70 feet total, I know it could be better but its all I can get away with for the moment. The ground is a rod thru the bottom of the sump where is always wet and I feel is good for RF, I hook the end of that to the back of the random wire tuner.
My concern is...the wire coming from window to tuner/rig is about 15 feet and due to placement I cant shorten it much more,
Should I use a coax from window to rig?
Or just leave it alone?
BTW I use low power about 30-40 watts CW and the setup seems to work fairly well on most bands..just concerned about loss and RF inside the shack.
Any input appreciated, and thanks for reading

Same setup I and many others used decades ago. One thing you might consider doing is to move the tuner to the wall where the antenna enters (sounds like you're in a basement?). You could adjust the tuner anywhere within earshot of the rig by using a noise bridge and listening to the noise while adjusting the tuner. The Palomar Tuner Tuner is made for just this type of operation. They can be had on the used market for about $60, or you can build your own. Don't use coax to connect between the tuner output and the antenna lead. You'll be effectively inserting a large capacitance to ground.

Gil,
If it's working okay, and it seems to be from what you've said, then I probably wouldn't bother to change the way you're feeding your antenna. There are probably several things that you could do to improve your system, but 15 feet of coax isn't going to make a lot of difference. But, the nice thing about it is that you could make the change and see for your self if there's any big differences (which will depend on the particular frequency). As for the RF exposure, at 40 watts, it just won't make any difference at all.

Ketalar,
Assuming that the antenna would be for receiving only,
just connect a single wire between the receiver and the
window frame. Don't worry about 'matching'. And a second
wire from the radio's ground connection to ground. Will
there be an improvement in reception? Beats me! But it
shouldn't be difficult to find out...

Yes George, I mispoke, you are correct
It says in very large letters on it " TRANSFORMER"
Since transformers are touted as being efficient
I was wondering how it would compare with
the normal tuner. Half of the challenge for me
was to come up with an inexpensive switching
system where the input was stationary while the rest
were switched thru and then repeated for the next
input e.t.c. With that being solved I look forward
to finishing and then playing with it
Regards
Art

A few years back, I reduced the number of control lines to zero with a wireless link. I used a tx/rx made for use as a garage door opener or some such remote control application. These were extremely simple devices that operate somewhere above 300 mhz. I boosted the effective range to over 30 meters by using a little 4 element quad on the rx. The transmitted signal was time division multiplex like used in any multi channel remote control. The tuner drive motors and electronics were powered by a 12 vdc gel cell that I kept charged by a rather large solar cell. You could also put your control signals on your coax, but I have never tried it.
Also used the garage door tx/rx in a remote reading field strength meter.

Try connecting your leads (both) to various points on the window,you might get lucky. I was able to achieve resonance with the windscreen
frame on a Sunbeam Tiger I restored. Luckily the spacing of the mounting studs were close to the right tap points.
Works better the the usual 1/4 wave whip!

I'd think the best examples come from dynamic systems, because the EM
wave is dynamic. In fact, you can define mechanical impedances, too.
You can have a long row of masses connected by springs, for example,
and spring force may be analogous to current, and mass displacement to
voltage. In a sound wave, the mass is the mass of the air (or other)
molecules, and the springs are the intermolecular forces (or elastic
collisions in air, if you will). Generally to propagate a wave,
you'll find you have two "state variables" whose states are
interrelated by differential equations, and the (a) solution to those
equations results in the description of the wave. The propagating
medium often has very low loss, and is propagating much higher power
levels than it's dissipating. So the (uV/meter)^2/377 has the units
of power, but that's not a power that's dissipated as it would be in a
377 ohm resistor...it's the power (at that frequency, or in that band)
per square meter passing that point in freespace.

The same is true, for example, of power going down a transmission
line, though the transmission line is much more dissipative than
freespace (unless it's made with superconductors). It's also true of
power transmitted by a driveshaft in a car: the torque you apply to
the input end twists the shaft, and that twist propagates down the
shaft. Yes, you can have reflections at the far end because of
impedance mismatches too.

I think a related concept is the difference between static (potential)
and dynamic energy. Both have units of energy, but they are rather
different things.

...

> Here we are again. Potential and voltage have the same dimensions, but

> an electromagnetic field can be just about anything you'd like it to be.

It took me a long time to properly internalize that. It's not just time-varying magnetic fields that cause trouble, either. A temperature gradient along the voltmeter leads can cause an EMF also, for example. A reminder: Kirchoff's voltage law is NOT that the sum of voltage drops around a closed loop is zero, but rather that the sum of voltage drops equals the sum of the EMFs in the loop. One such EMF is because of any time-varying magnetic field enclosed by the loop (and therefore may be different if you move the leads), but others are chemical and thermal (actually two distinct thermal types). Both EMF (electromotive force) and voltage drop have the units of "volts", but they are not the same thing. I do like the statement in terms of a closed loop much better than thinking about it between two points, because Faraday's law says only that there is an EMF in any closed loop enclosing a time-varying magnetic field, and that EMF is proportional to the rate of change of the magnetic field. It does not say that the EMF is uniformly distributed, nor that it is in any one place, only that it exists. And Kirchoff's voltage law gives us a way to apply that EMF (and any other EMFs which may also be in the same loop because of other things happening) and understand why we see voltage drops around the loop. Ohm's law tells us a lot about how the drops will be distributed, according to the resistances in each portion of the path. Faraday's law applies whether there is a conductor in the loop or not. If there is a conductor the whole way around, the EMF will drive a current in it--and that current will create a magnetic field to oppose the one creating the EMF.

Cheers,
Tom

I'm surprised no one has suggested a coupling loop. Small loops are often fed via a smaller loop placed inside the main loop, typically off center. The impedance match can be effected by adjusting the size and number of turns of the smaller loop. I believe one of Reg's programs helps with the design of these.

Tom Bruhns pointed out in an email that the statement quoted below isn't a very good example. Because the mass of the Sun is so much greater than that of the Earth, the Earth's orbital velocity isn't significantly affected by the mass of the Earth.

So I'll restate that as follows:

The distance between the Earth and the Sun and the orbital velocity of the Earth are related, but distance and velocity aren't the same thing.

Or,

The mass of the Sun and the orbital velocity of the Earth are related, but the two aren't the same thing.

You get the drift.

Thanks, Tom, for pointing this out.

Yes, that's the one.

I possibly have a photocopy somewhere, but don't recall seeing these extra details, which Roy may have hard directly from Wes:

> If I recall correctly, he concluded that either a two-band solution
>could always be found, or that he wasn't able to find a combination
>that he couldn't find a two-band solution for.
>

If anybody's interested in this "two bands, one coax, no switches" solution, I'll try to put a PDF together over the weekend (it isn't a good subject for ASCII art). It also struck me that this may be a good subject for an Excel spreadsheet, or one of Reg's programs.

I'm planning on putting up a 130' inverted V antenna at my new QTH. I will be operating QRP with my Yaesu FT-817 and LDG Z-11 autotuner. The top of the V will be about 40' in the air and the ends about 12' in the air. I will be using 16 ga wire for the antenna. I plan to operate SSB/CW/PSK31 mostly on 20 meters with some nighttime activity on SSB/CW 160 & 80 meters.

My question is this:

Should I feed it with 300 ohm HD twinlead, 450 ohm ladder line with or without a Bal-Un or rg58 coax with or without a Balun?

Sorry if this is a dumb question but I wanted to pick the brains of the experts. My thinking is to have the antenna
fed directly from rg58 coax (no Balun) and let the tuner do the work.

Feedline radiation causing RFI/TVI is not a real concern at 5w, right? The '817 seems to be an acceptionaly clean transmitter - my TS200X and TS530S cause RFI in telephones and PC speakers even when turned down to 5 watts - my FT-817 causes no TVI/RFI at all!

That antenna models with a 40:1 SWR on 20 meters. I think you better use ladderline or the losses in coax will be outta sight.

I like ladder line to a 1:1 balun to a short piece of coax to the antenna tuner. Should work 80-10 nicely.

If you want to approach the limits of efficiency, feed it with open-wire line, usually around a Z0 of 600 ohms. Feedline length will be important. IMO, use a 1:1 balun/choke at the tuner output.

I never said that the E field IS a voltage, only that they are
related, and that you can measure the strength of the E field by
measuring voltages, which is what you really do with a field strength
meter anyways.

Are you saying that Newton*Meters are different depending on the
situation? I don't think so. A Newton is a Newton. A meter should
always be a meter. And an Ohm should always be an Ohm.

I'm not saying that the impedance of free space is relating
voltage to current, because there is no current flow in free space.
But why do they use the same units (Ohms) to describe the relation of
the E field to the H field?

Hugh Skilling - "Intrinsic impedance is somewhat analogous to the
characteristic impedance of a transmission line. It has the
dimensions of Ohms, for the E is Volts/Meter and H is Amperes/meter."

Perhaps I'm asking the wrong NG.

> field is "related" to voltage, it's equally related to distance, force,
> and charge. You can, in fact, find a bundle of other equivalent products
> and quotients of units that are equivalent.

The E field is certainly related to all these things. If you could somehow accurately measure the repelling force on a unit positive charge, that a static positive charge exerts upon it, then you would know what the E field is in Newtons/Coulomb, which would also be the Volts/meter.

If you could also measure the voltage potential of this unit positive charge in the same positive field, at two different points that are 1 meter apart (normal to the gradient of the E field), then you should get the same answer as above.

This second situation is what i'm asking about when i say where would the 1uV be measured. But in the real world, it would seem that most field strength meters have amplifiers (LNAs) either before or after rectification by Schottky diodes.

A field strength meter seems to relate the received power with the field strength, but not actually measuring the uV/meter directly. Certainly they must calibrate these instruments with a known amount of power into an antenna of known characteristics, in an anechoic chamber, at a fixed distance away, etc.

I was simplifying the situation with the static E field case, but
the change of 1uV for every meter moved normal to the gradient of the
field can also apply to the AC situation, except that the +/- 1uV
would apply the RMS values.

> voltage.

Consider a mass on the end of a spring compared to an L-C tank
circuit.

The mechanical equivalent of inductive impedance would be simply
the mass. That is, the resistance to the change of current compared
to the inertia of a massive body.

The spring force would be analogous to the voltage charge in a
capacitor, not the current.

The velocity of the mass is analogous to the current in the tank
circuit.

The displacement of the mass is analogous to the total stored
charge in the capacitor. I.E., max displacement corresponds to max
charge storage in the cap, with the corresponding max voltage and max
force from the spring (fully stretched or compressed).

Ian, count me in. While "all band" operation is always desirable, when
you get right down to it 160/80 or 80/40 are the gaps I'm really
trying to fill. And while many of the other solutions proposed are
innovative and tempting to perform, the "keep it simple" approach has
very strong appeal.

Cecil, if I go back in time a long way, to the days of transformer design, I recall that core loss increased as an exponential of frequency. The exponential was greater than '1.2' and less than '2.0'.

Now, magnetic materials have changed, since the invention of the wheel, but I still suspect that losses in magnetic materials are exponential, even in new materials.

So, in a transformer I would expect core loss to increase exponentially from 1.8 to 29.7 MHz.

In a balun, well I don't know!

Shortly after the invention of the wheel I came into the ownership of a B&W air wound balun rated at 250 watts continuous that I used for over 35 years. I dumped it as part of the move from Massachusetts to New Hampshire. That was DUMB! But, using air instead of magnetic material certainly minimized losses <grin>.

Back to the Modern Age. How efficient is a transmission line transformer? [TBD %] Can you quantify a suitable number or will it remain a qualitative statement?

Looking at some of the graphs in Jerry Sevick's book, _Transmission_
Line_Transformers_, it looks like about .05 dB maximum loss from 3
to 30 MHz. Note that figure is for perfectly matched resistive loads.

A transmission line transformer carries a high flux density for common
mode but not for differential mode. An ordinary transformer carries
a high flux density for differential mode. That's got to make a
difference.

Hi Dave,

Jerry Sevick offers a multitude of designs, all specified for loss over frequency. One such example illustrated in Fig. 11-6 shows a 50:12.5 Ohm with an insertion loss of around 0.1dB or less over the interval of 100KHz to 30MHz. And this is not the best example of low loss.

Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.antenna,rec.radio.shortwave

Ce-mag.com is the world's foremost on-line resource for international developments in regulatory compliance for electronics engineers.

In the latest issue BPL, PLC and PLT covered in very great detail from the regulatory stand point.

http://www.ce-mag.com/archive/03/ARG/hansen1.html

http://www.ce-mag.com/archive/03/ARG/hansen2.html

Brief excerpt (Conclusion)
"PLC technology, in principle, is potentially attractive, if it were to become compatible with existing telecom technologies. PLC technology is still premature in terms of EMI prevention. PLC has little to offer over the competitors and certainly does not justify more EMI.

Standards will evolve relatively slowly. The requirement of the EMC Directive with harmonized norms (to conducted EN 55022) are not met by most PLC systems, regardless of the stricter limits of regulations such as NB 30.

It is unlikely that PLC will experience widespread application under its currently implemented status. With delays in implementation and lackluster client acceptance, even the business case is becoming less attractive."

The article is written from the European viewpoint but very relevant to BPL.

I guess I should have been more specific - I already
have an effective 20 meter antenna and am looking
to add at least 80m and hopefully 160 capability to an
existing area available for setup. I also might like to
go on 40m at 13:30 MDT for a net and work the
WARC bands every now and then.

But, hey - thanks for the input. :-)

I never said that the E field IS a voltage, only that they are
related, and that you can measure the strength of the E field by
measuring voltages, which is what you really do with a field strength
meter anyways.

>

>

Are you saying that Newton*Meters are different depending on the
situation? I don't think so. A Newton is a Newton. A meter should
always be a meter. And an Ohm should always be an Ohm.

I'm not saying that the impedance of free space is relating
voltage to current, because there is no current flow in free space.
But why do they use the same units (Ohms) to describe the relation of
the E field to the H field?

Hugh Skilling - "Intrinsic impedance is somewhat analogous to the
characteristic impedance of a transmission line. It has the
dimensions of Ohms, for the E is Volts/Meter and H is Amperes/meter."

Perhaps I'm asking the wrong NG.

> and charge. You can, in fact, find a bundle of other equivalent products
> and quotients of units that are equivalent.

The E field is certainly related to all these things. If you could somehow accurately measure the repelling force on a unit positive charge, that a static positive charge exerts upon it, then you would know what the E field is in Newtons/Coulomb, which would also be the Volts/meter.

If you could also measure the voltage potential of this unit positive charge in the same positive field, at two different points that are 1 meter apart (normal to the gradient of the E field), then you should get the same answer as above.

This second situation is what i'm asking about when i say where would the 1uV be measured. But in the real world, it would seem that most field strength meters have amplifiers (LNAs) either before or after rectification by Schottky diodes.

A field strength meter seems to relate the received power with the field strength, but not actually measuring the uV/meter directly. Certainly they must calibrate these instruments with a known amount of power into an antenna of known characteristics, in an anechoic chamber, at a fixed distance away, etc.

I was simplifying the situation with the static E field case, but
the change of 1uV for every meter moved normal to the gradient of the
field can also apply to the AC situation, except that the +/- 1uV
would apply the RMS values.

2369. Opinions please G5 against long wire against windom?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-31 09:31:38 UTC
From: Chris Bartlett <Bartty@v21mail.co.uk>
Message-ID: <3f290b8d@news.greennet.net>
Source record: 111513

Hi all. My G5RV fell down the other day. The feed point was half way down the garden. for the moment I have put up a long wire (about 40 yards) and am able to operate on all bands using my tuner. The advantage here is that the feed point is near the house.

I had been considering trying a Windom. The measurements I have are 82' and 51' and a feed from a 1 to 1 balun 22' coax to a 4 to 1 balun at the T point. I also have different measurements of 85.1' and 36.4' fed straight to a 4 to 1 balun. The second would probably be the easiest to set up. But would it be the best?

Anyone with experience with home brew Windom's and opinions please.

The Windom would allow me to keep the feed point near to the house.

Thanks,

Chris.

Doug;
Universal does not have a web site. They seem to be satisfied with AES
& Texas Towers being their only dealers.
After Hurricane Hugo damaged several towers in the Metro Charlotte, NC
area in 1989, several club members ordered Universal 60' & 70' models
and are very satisfied with their quality.
Good luck,
Jim, K4SQR

One alternative could be a 102' g5rv, which is tuned for 20 meters, to
begin with, and also could do 80 with the tuner. Dunno about 160. MFJ
makes one for $39.

Of course, you can also measure the strength of the magnetic field (of
an EM wave) by measuring a voltage. (Which may be what you are doing
with a field strength meter, rather than sampling the electrical
field, depending on the meter.) And you can measure a temperature
(differential) by measuring a voltage. And you can measure
reduction-oxidation potentials by measuring a voltage. ...

2377. I have an antenna transmission line problem

Newsgroup: rec.radio.amateur.antenna
Date: 2003-07-31 20:47:16 UTC
From: larry <larya24@hotmail.com>
Message-ID: <offWa.33277$hOa.16245@news02.bloor.is.net.cable.rogers.com>
Source record: 111420

Greetings

Lets see where do I start. I have been licenced since I was 16, in 1964. My ham startion was located in the basement. My first antenna, a random wire, ran from my antenna coupler, an L network, along the basement ceiling out a hole drill in the frame of a basement window, up to, and over, the eavestrough and down the backyard to the cloths line pole. About 75 feet. Worked great on 80, 40, 20 meters.

Since then a pine tree located this on the house side of the pole has grown to all but block my route to that pole.

Lots of time has gone by plus interests, etc, and I am planning a return to hf, perferably cw.

My ham station has now moved from the basement, same house, to my old bedroom facing the back of the house. My bedroom in now at the front side of the house.

The most direct route to the back yard is now via a window. The window has a permanent screen on the outside, it can be removed for changing, repair etc. On the inside is a weather designed up and down sliding glass window.

My question is: is it possible to design something to allow me to pass a transmission line, of any type, through a screen window, without significantly effecting the characteristics of the transmission line and without effecting the integrity of the screen window?

A windom or an OCF (Off center fed) antenna work well. If you put up a
wavelength for the horizontal part you can work it on even harmonic bands.
It will work elsewhere but you may have feedline currents this way.

My first hb windom was 130 foot long with a single wire feedline, 1/3 of
the way from the end. I used a simple homebrew pi-net tuner. Worked great.

At another time I used a OCF dipole, this antenna I used 200 ohm twinlead
(military stuff). Fed at the 1/4 wave point and it did a decent job too.

Unfortunatly I cant compare them to anything, since they were the only
antenna I had up at the time.

So, my advise it put it up. See how it plays, and then tear it down and
try the other one. Thats what makes ham radio so much fun. Enjoy.

Dan/W4NTI

Ketalar wrote:
"Which one to start with?"

Kraus says that a rectangle such as a metal window frame can be considered as two 1/4-wave stubs joined together and fed in the middle across the narrow dimension. However, Kraus says the stubs are a poor radiator, but if the stubs are the edges of a large conducting sheet, the current can spread out making the slot a good and efficient radiator. See page 305 of the paperback edition.

You may not need much efficiency for good reception. Folded monopoles work just fine for both transmission and reception. I think something could be worked out as folded monopoles back to back.

Best regards, Richard Harrison, KB5WZI

Larry,
Right off hand I would say use a 'bulkhead' connector
through the screen. You might mount the connector on a
piece of plastic/metal/wood on each side of the screen to
keep from tearing it. Sort of a jelly sandwich with the
screen as the jelly (if that makes any sense). Hows that?

www.universltower.com is the web site for a Universal Tower in Henderson KY.
It will not come up. You could always try calling them on the 'phone, or ask
the Texas Towers sales rep what the story is.

Heathkit used to make a small metal container that held resistive
transmitter dissipative units, surrounded by oil, that would take all
transmitter power, and the SWR was nearly 1:1 on all (HF) bands.

I think that is what you want here.

I had the local hardware store replace the metal screen with nylon screening in a similar color. Fiberglas screening would have been equally good. My antenna is fifty feet of (almost invisible) No 30 wire, which fits easily through the screen.

All this time, I thought it was a Byrd wattmeter. I mean, if we are talking details here, then let's get it right. Right?

Dave
KZ1O

p.s. And before you give me s**t about this, look below where he says "70.7 volts". Down to three digits of accuracy, but the spelling is wrong (in fact, a copyright violation) two words later.

Come on, do the Math (and Spelling).

The output of the element is a function of both voltage and current at the point it is measured. The element sums 2 voltages, one that represents the voltage at the point of test and the other that represents the current. When SWR is 1:1 these 2 voltages are equal so that the voltage output is actually twice that of what is contributed by voltage alone at the point of test when measuring forward power. This is why it would be zero when measuring reverse(the voltage representing the current adds negatively). In the hundred watt example you used the voltage out to the meter would be 141.4v not 70.7v

Hi Jim,

Cynical? This 0.1dB corresponds to about 2% error from perfect where too many think that 5% error is the worst they have to suffer from making a power measurement with their Bird (which actually doesn't do nearly that well in the first place due to these accumulations of error). It doesn't take long for error to accumulate to the 10's of percent where you couldn't convince the bench tech that he has too many places of precision in his pronouncement of measuring 104.5W (when it was in fact closer to somewhere between 85W to 115W).

I can well anticipate the "so what?" rebuttal. "Who needs 5% accuracy?" being another. The general rule of thumb demands that your standard exhibit 3 times the accuracy of the instrument being calibrated (the Bird is already dead on arrival using this 0.1dB loss, if it were not characterized already). With an out of whack Bird, you barely qualify any power measurement to within 15% (and there are more sources of error than the BalUn used to isolate the Bird). Again, I am being generous with the 3 times rule (professionals generally seek 5 times and are more comfortable with 10 times). But this is all really the provence of the professional Metrologist, not the Amateur. For the Bench Tech that confidently made the 104.5W measurement (not knowing it was in fact closer to 60W) would hardly know it through contacts where they barely noticed the less than 1 S-Unit difference.

Returning to this 0.1dB, it also represents a heat burden of 20W (or more, I am being generous) for each 1KW passing through. This is a lot of heat for small packages carelessly regarded as being trivial (after-all, who can see 0.1dB on their S-Meter?). There have been more than single reports of Hams writing here in astonishment of their BalUns exploding. Blame the BalUn seems to be a popular ballad played

to that audience. Others pronounce with hushed tones of reverence remonstrating mankind for drifting from the true path of the air wound BalUn (or choke, what will you) mindless of the same loss, but gratified through ignorance of the greater heat mass.

This 0.1dB in the wrong hands is clearly an example of extravagant dismissal or myopic attention. And speaking of hands, how long would you consider it trivial if you had to hold onto the sucker for 20 seconds?

2396. Building AUTO TUNER

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-01 07:21:14 UTC
From: Jimmy <Gfender@carolina.rr.com>
Message-ID: <KxoWa.317020$_w.12741753@twister.southeast.rr.com>
Source record: 111440

I would like to build my own auto tunner and need info on software. My plan is to use a car ecu computer for the controller as it already has much of the digital an analog interface I will need, is rugged and cheap at the local scrap yard. Before someone yells "why are you using that for a controller", the point is to use one for something other than its intended purpose. I just thought an automatic antenna tuner would be a good use for one.

Have for sale a Hy-gain 20 Meter 4 Element Yagi Model 204BA in excellent shape with all new stainless steel hardware. The Yagi is down disassembled and ready to go. Asking $200, new the antenna is $540. It is in perfect shape and the SWR is outstanding all across the band. Went to a log periodic and getting rid of my monobanders. Can ship if the buyer is willing to pay shipping charges. Live in Central New Jersey.

Yep, I bought an SGC-500 amp and didn't want to spring for a high power
tuner. So I vary my window-line length to obtain a match.

When I retired from Intel, most ecu controllers ran their programs from
internal ROM which is not reprogrammable. Seems something like a PIC
would be a more logical choice.

Are you certain the problem is not insufficient current capacity through the DC cables. I had this exact same problem recently on a boat. Voice peaks distorted- the only problem was that the DC connection had too much resistance.

I'm just curious. Roy? What the heck are you talking about? I mean,
I can see you're talking about feeding a magloop, but what does that have
to do with feeding a random wire from a basement?

2405. PM magloop - Ideas, success/failure stories?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-01 15:15:26 UTC
From: Tim Conway <n9hmg@mailhot.reversethatanddropthis.com>

Source record: 111450

I'm thinking of taking the insulator and center conductor from coax and sliding it in and out of a copper tube, maybe with threaded rod to hold position and facilitate fine adjustment. I'm figuring on copper tape on a hula-hoop as the loop, with the cap mounted directly to the hoop, and copper foil tying the sides of the cap to the loop so I don't have to halve the capacitance with a dual-plunger reimplementation of the butterfly. What kind of capacitance per inch can I expect? Would a 36 inch diameter loop at 5 watts make enough voltage to puncture rg-58? rg-8?
If it'll take a lot of sliding, I'll have to switch to dual-plunger to avoid excessive conductor length and flexing.

I plan to mount it on a backpack, using dowels, or maybe PVC, to elevate it for a foot or so seperation from the metal pack frame - cap at top(another reason to keep the cap light). Will tuning change a lot depending on whether the pack is worn? I really don't want to have to add motorized tuning so I can tune it while worn... weight, don't you know?

One other possible deviation - I'm considering carrying it flat. My width will be unchanged, but it'll lower height by 18" or allow another 18" of elevation, and give me an omnidirectional horizontally-polarized pattern, right?

At 5W, I'm not concerned about heating, and even any RF burns should be manageable, but I want to be as efficient as I can be within the constraints of /PM operation.

If I can successfully build this, I'll try to document it well, and make the design available to others. At the very least, maybe we'll get some cool ideas.

73,

tim

"Jimmy on reading the postings over time I see a lot of
people asking about the G5RV which is an inexpensive way of
of operating on many bands. I thought that maybe a inexpensive way
of matching such an antenna would be a cheap sort of tuner.
I don't need a tuner, it was just an idea that popped
into my head. Clark raised the subject of excess heat
that I hadn't thought of but I am enjoying the challenge
of putting together suitable mechanisms that would not be
subject to breakdown, that one could place at a antenna feed point.
If it explodes it would be more spectacular than having a
neon light blinking during radio operation !
If one must have 1: 1 SWR at all times then they can spend a $200
amount or more to buy the SGC tuner (I thing that in the name
of the automatic tuner which I believe is limited with respect
to power.)
The mechanism I am making is a star shaped wheel with a slot in
each point.
It has a interconnecting rotary switch that sweep each transformer
connection and when it has rotated once engages the star wheel
so that it rotates a distance equal to the transformer connection
where it stays in place for the next rotary switch rotation.
Making the parts from a plastic sheet used to replace a glass
window pane plus the use of a small hand grinding tool.
Duing this in the garage to escape the heat

First off, if the the inside diameter of the tube is about the same as the inner diameter of the coax shield that you took off, then the capacitance per inch would be the same as what is specified in cable charts. For instance, RG58 is something like 29 PF/foot.

I wouldn't bother with fancy threaded rods. Slit the end of the tube, and fasten a small hose clamp down on it to keep things in place.

Lastly, what you describe is how CushCraft seems to build their gamma match, and they take hundreds of watts. They adjust the capacitance by sliding the insulated wire in and out of the tube. This will have limited range; so, to get it in the ballpark you would have to keep cutting pieces off the end. For good measure, melt some insulation on the end of the wire so it is not exposed.

I have a Denon 2500 receiver. The small external AM loop
doesn't work well.
Would just connecting about a 100' 12 ga wire to only one of
the terminals and not grounding the other (too inconvenient)
work.
Or are there better external indoor loops out there?

2411. Butternut HF6V For sale or trade

All hardware, with coax matching section. Includes the 12 and 17m add-on kit. Antenna last used during Field Day with no tuning problems whatsoever. Anti-ham condo management forces sale. Would like to trade for any of the following:

Yaesu MD100-AX8 desk mic,
INRAD 6 khz AM filter for Yaesu FT920
HF/6m antenna tuner with random wire capability
W2IHY 2 band EQ

or sell outright for $125 US plus shipping from Ontario
Please reply to my personal e-mail at ve3tmt@yahoo.ca

I also have an MFJ249B analyzer I might trade for ???

Source record: 111457

Do a search for "Shielded Loop". Your 100' of
wire would be a improvement over the small loop
that you have, but less than 50% of a quarter wave
for 1100 khz (the middle of the AM broadcast
band). The loop will be directive, and you will
need to be able to adjust its tuning for maximum
efficiency but it will work gang busters for you.
For FM the folded dipole that Radio Shack sells
(420-2385) for less than $5.00 works like
gamgbusters. Put it up as an inverted V and
enjoy.

Cecil, the idea that you have is quite unique but I was thinking
of the newby ham. To capture the future hams of tomorrow we must
enable them to get them on the air as quickly and cheaply as
possible and not dissuade them in any way as to how much they
will be paying in the future, and that is where my thoughts lie.
If a newcomer is to put up a G5RV so that he can get on the
air quickly,I thought that buying a RF transformer would be a
quick way of getting on the air and getting the taste for ham radio.
To be honest Cecil no newby is going to struggle with your method
in his early days.
If one could arrange a way to run thru a series of impedance ratio's
with just one knob then we have hooked those who are curious, even
when using the most plainess of wires or the gutter we have fed the
mind, remote control systems can come later. Frankly when you are
hooked by ham radio money ceases to become an issue.

I think it all boils down to signal to noise.
If you are trying to communicate with another station and he is putting out
100 watts and is not being copied and then he puts out 110 watts and you can
copy him that is what counts.

Thanks, Tam. I wasn't sure if there would be a difference going from
braid to solid.
On the cutting: I'm going for a really broad range of capacitance, which
is another factor for the threaded rods, as they can hold things steady
even if I have the coax nearly all the way out of the tube. I know such a
cap could handle a lot of power, but remember, a magloop runs at a very
low internal impedance, which means really high current AND voltage. I'm
not worried about dialectric melting, just puncture. Most magloop designs
I've seen call for 3kv breakdown voltage for 50 watts. 50 ohm coax
handling 1000W is carrying about 4.5A at 224V, RMS, so what is that, about
320V peak? Let's say they rate it for 100% safety factor at the legal
limit, so a round 1000V? Yeah, I guess you're right, about any coax
should handle my measly 5W, though I don't think voltage scales linearly
with power in a magloop... maybe with the square? That'd put me a bit
under 1000V. Heck, the worst that could happen is that I could lose my
only rig, and maybe get a nice RF burn, right?

So, what about radiation pattern and body tuning?

Actually, I wasn't looking for an apology, but for a pointer back to the thread... it sounded interesting.
Now that I know which thread, I must point out - wouldn't trying to run a window frame as a magloop be a big dummy load? I'd think he'd be better off loading it as a capacitative plate. The high currents in a magloop going around that aluminum, and crossing what are probably just butt joints, would dissipate nearly all the power as heat.
Now, hanging a
picture in a frame made of copper pipe and feeding that would be a whole new ball game.

Roy brought up a point on another thread by accident. Try using it like a magloop, and set a feed loop inside it. Once you're using it with circular currents, you'd do well to improve the electrical connection between the segments, as most window frames aren't assembled with an eye toward conductance.
Incidentally, you do intend this as a receiver only, right?

Tim,

The voltage rating on coax is a lot higher than what you would calculate based on max power. I can't find the numbers right now, but seem to recall that RG58 was rated at 750 V or more. The big stuff is good for over 2000V. The reason you don't want the end of the wire exposed is that it could lead to arcing or corona. Probably not at low power, though. Sorry, can't answer your other question.

==========

Bill, sorry to be so pessimistic.

If, because of bad signal to noise ratio you can't copy him when he's using 100 watts, then, as sure as eggs don't bounce off concrete, there's no hope of any detectable improvement by increasing power to 110 watts or 0.4 dB.

Suppose when he's using 100 watts you can hear only 25% of words (or morse characters). So you can't copy him.

If he doubles power to 200 watts you will still read only 40% of what he says. So you still can't copy.

If he doubles power again to 400 watts you will be able to copy 60% of what he says. You will still be in big trouble.

At 800 watts 80% of words (or characters) will be OK but it's not solid copy. Requests to repeat will be common.

At 1600 watts 99% of words (or characters) will be OK and that's solid enough.

There are many assumptions in the foregoing crude analysis. But as many have experienced it is typical.

Claude E. Shannon's (of Bell Labs) original classical paper on the subject of "Communication in the Presence of Noise", Jan. 1949 can be downloaded (I have just discovered) by doing a Google on the title. Radio and phone engineers had been trying for 40 years to describe in precise mathematical terms the effects of noise and cross-talk in a communication channels. The transistor had just been invented. So had PCM pre-war. But progress in the design of the vast communication digital networks then envisaged and which we now see was being impeded by the lack of understanding of the effects of ever-present random noise.

It was basically a problem in Statistics. But Shannon went off at a tangent back to Geometry where Pythagorus the ancient Greek had begun. He translated the statistical problem into one of calculating the number of small spheres

which can be packed inside a much larger multi-dimensional sphere. The calculating procedure acquired the everlasting name of "Ball Packing". It is not difficult to understand. It was Shannon's dazzling multi-coloured flash of inspiration which did the trick. His name has gone down in history. Think of him the next time your electric light dimmer-switch goes faulty. Following Shannon progress forged ahead. In-words such as signal-to-noise ratios and error-rates became very popular.

A one-dimension sphere is a dot. A 2-dimension sphere is a flat circular disk. A 3-dimension sphere is a ball. Followed by N-dimensions, all of which have a surface area and and a volume involving Pi.

Reg.

2429. Re: Irrigation pipe for antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-02 04:15:47 UTC
From: Don <europa@bendcable.com>
Message-ID: <3F2B3AF3.19651E24@bendcable.com>
Source record: 111379

Hastings Nebraska is not the east coast, but the site below is reputed
by amateur astronomers to be a good source for aluminum tubing:

http://www.hipco-ne.com/scope.htm

It wouldn't cost anything to find out. Get a 100' roll of stranded #16 or so wire at RShack, attach one end to your antenna terminal, and unroll the wire. See what happens. I used to get good results with a piece of random length wire on the old AM receivers I started out with.

>have experienced it is typical.
>

Typical for a machine, but not for a human being. For humans, "copying" very weak speech or Morse is mostly about *understanding* it as language.

In conversational speech, we don't always hear every word. Our minds are remarkably good at filling in gaps by using the broader context of the whole sentence. Even if you don't hear a word clearly, you can hear a word was there and your mind will automatically make a good guess, based on what we did hear before and after. It happens all the time, in conversations both on and off the air, and you don't even notice yourself doing it.

It's more obvious when copying Morse, where we more often fill in individual letters, but sometimes also whole words. We make very clever guesses about what the letter could have been, based on what we did manage to hear.

Often there is a threshold effect. Below that threshold, you can hear quite a lot but it doesn't make sense as language. Just above the threshold, it clicks into context and you can understand a whole stretch... and then maybe we lose it again.

It's also like listening to a language we only "half" know. That doesn't mean we understand a certain percentage of individual words, as a machine might. The way it really works with human beings, we're suddenly delighted to find ourselves understanding whole sentences... and then,

just as suddenly, we lose it again completely.

The exceptions are for certain key items like a callsign, name, QTH or contest exchange. These items come one by one (without context) and must be logged with 100% accuracy, so then it's rather more mechanical like Reg describes. But even for key words like phonetics, there is a threshold between hearing a sound, and that sound resolving itself into a recognisable word.

As any DXer knows, the threshold between "getting it" and "losing it" can indeed be as little as 1dB. The more serious you are about working right down to that threshold, the more that last 1dB matters.

>which provides freq (160M-440) vs. power handling ratings for BNC
>connectors?

I don't know about a website, but it has often been discussed here. Try searching through
http://groups.google.com/advanced_group_search

It all comes down to the RF current through the center connection. This is partly about skin effect and surface conductivity, but equally important - and less predictable - is accurate assembly of the center pins.

If at all possible, use connectors with captive center pins. This removes the biggest source of inaccuracy in amateur assembly.

All the contact pressure in a BNC derives from the rubber washer inside the bayonet ring. A good BNC should need quite a hard twist to make the bayonet click into place... and in old surplus plugs, this springiness does wear out.

Bottom line: BNCs in good condition are fine for 100W at 440MHz, so they're good for that power level at any lower frequency too.

I bought a number of 40 ft. lengths of standard 3" and 4" O.D. x ~
0.060" wall aluminum irrigation tubing a *lot* of years ago which I
used to build a half-dozen or so fullsize two element 40M Yagis for
fellow members of my neighborhood dx contesting club. These were big,
heavy antennas with 70 foot long driven elements and I used the 4"
material for the 20 foot booms. Irrigation tubing supply sources were
all over southern New Jersey which is known for it's vegetable farming
and is where I bought mine. I've seen fields full of Al irrigation
tubing in Eastern MD which is a bit closer to Richmond. There are East
coast sources, ya gotta poke around.

I still have one 40 foot length of 4" tubing and one 40 foot length of
3" tubing. I need to get rid of them and I'll be glad to donate both
gratis to any licensed ham who will cart them off and get 'em out of
my life.

2440. Vee Beam info needed

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-02 12:48:48 UTC
From: Sgordon <noshoes2@yahoo.com>
Message-ID: <QqOWa.15274$Vx2.7749441@newssvr28.news.prodigy.com>
Source record: 111384

Considering putting up a Vee Beam for 17 meters. I then ran across a couple websites that show a multiband Vee Beam cut for 15 tuning it for 6-20m. Has anyone built even a mono-band Vee Beam? How did it preform?
If you would cut one for say 40 meters and feed with opern wire, how will it preform on the higherbands? Just really looking for some more info on them.

There's a fair amount of info on V-antennas in the 15th edition of The ARRL
Antenna Book including sloping terminated V's.

Source record: 111386

And we can look at it going the other way. I can run my FT-817 with its 5 watt signal for a lot less money than my friend Jim can operate his kilowatt. If the band is open The difference between my 5 watt signal and his 1000 watt signal is 2 or three S units at the far end of the circuit. Not enough to be really noticeable. If the band is closed, nobody is talking long distance, the band is closed. Now when conditions are marginal he has a decided advantage. Right now I am happy burning a kilowatt of power purchased from the electric company every 15 hours while he gets about 20 minutes operating time for his station for the same dollars.

>Best regards to all,

Hi OM,

Odd no one has actually answered your question.

However, it pretty much depends on the physical dimensions of the window frame (does the sash present a moving short across it?) before a solid value would work. You also suffer a potential problem of it pointing the wrong way to serve your needs (how would you tune it, if it didn't hear anything?). Also, where you put the Gamma match would also affect how it tuned up.

Another point, if you just made the match a little longer, threw away the capacitor, and screwed it to the wall instead; then it would probably do just as well.

Hint: you may solve your problem more with height (put a simple dipole up higher) than with tuning.

I think the outfit in KY is somebody else. I found Universal Tower.
www.universaltruss.com is located in Clinton Township, Michigan. As the name
implies, their big thing is trusses. Did not see any info on towers. Address
matches that for Universal Manufacturing in the AES catalog. The AES cat.
says they are shipped FOB Mt. Clemens, but that appears to be the same place
if you look at their map.

Actually only the morse operators will have half a chance of operating if the BPL goes through. They need the least amount of signal to be able to communicate. I am primarily a phone operator. I need to get my comments in. Off to do that now.

I have new in the box Antenna Specialists MON-4 ground plane for scanning 30 - 50 MHz. It seems to be just a hunk of metal, no coils, etc. Any reason why I shouldn't cut it for use with my 6 meter rig? Can't find any details on their web site. It has to be 1970's vintage 1//4 wave ground plane. Got it from my father in law years ago. He was a volunteer fireman

But will the BPL give the Pactor something else to grab hold of? I do not know - just asking. My radio station goes into a briefcase and the computer does not have a sound card, or would be able to figure out what to do with it if it had one. It is a R/S TRS 80 Model 100. It can handle packet, I don't know about other digital modes. Into the brief case goes: FT817, Paddles, R/S DSP unit (I know it ain't great, but it helps), MFJ259, Small Tuner, Crappie Dipole, Super Antenna MD-1, R/S Computer, KAM 3, Solar Panel, Coleman Jump Battery. Have Station will travel.

BNCs are almost universally used for non microwave test equipment. So, I have used them a lot. My biggest problem has been the shield not making good contact with the body of the connector after a while. By far, I have had the fewest problems with the kind where a sleeve is crimped over the outer insulation to provide strain relief. On the better connectors, this sleeve is about an inch long. You do not want to allow any flexing of the bare shield.

Actually I would think a newbie would be the one most likely to embrace
Cecil's method. Its the guys who have been around a while who want
everything controlled at their armchair(like me). This is not to say that
Cecils method could not be controoled from the shack, Just replace some of
those switches with relays and maybe make some custum impedance feedline for
even a better match that what he shows though you dont really need it. This
sort of setup could even be controlled by a lot of radios that provide for a
means of automatic antenna switching.

Vee beams, being basically half a rhombic, are not really cut to any
one frequency.
The only real consideration as to length, is to the amount of gain you
will get.
That will vary on the length of the wires per wavelength of the
frequency being used at the time. You can use one on any band, if it's
long enough to qualify as a true vee beam, but you would design the
length for the amount of gain you want on the lowest band to be used.
One wave per leg would be the minimum, and that's not much of a vee
beam. Most are multi waves per leg. Feeding with a tuner and open wire
line as you suggest will be fine, and is the usual method used. The
higher the freq, the higher the gain in general. The angle between the
wires needs to be considered though. In general, the longer the
antenna in wavelengths, the smaller the angle between the wires for
optimum results. MK

If you're going to spend money, then be sure to buy plugs with a captive pin and pressure-sleeve ("top hat") cable clamp.

They are more expensive than the original MIL type, but much better for hand assembly and much easier to remove and re-use... in other words, they're good long-term value for amateurs.

An example is the Tyco/Greenpar 1-1478401-0. There should be a disassembled picture at www.farnell.com/uk - search for part number 3977754. (The parts aren't laid out in quite the right order, but you'll get the idea.)

Personally I wouldn't use crimp connectors without the correct tools to make the full six-sided crimps in the two different sizes required. Also they cannot be re-used, which makes them poorer value for (most) amateurs.

Sounds kinda like you want a "venus ham trap"....:/

> If a newcomer is to put up a G5RV so that he can get on the
> air quickly,I thought that buying a RF transformer would be a
> quick way of getting on the air and getting the taste for ham radio.

I think stringing up a coax fed dipole is about the easiest of all
antennas.

> To be honest Cecil no newby is going to struggle with your method
> in his early days.

I'm sure many would. It's not that hard to rig up.

> If one could arrange a way to run thru a series of impedance ratio's

Huh??? I thought this was already solved in my previous post where I
reinvented the L network. Even the poorest of hams can likely scrounge
an oatmeal carton.

Frankly when you are
> hooked by ham radio money ceases to become an issue.

Luckily, most antennas can be built for fairly low cost.
Now radios.....:(
I'm too lazy to build radios when nothing I can build is as good or
better than what I can buy. MK

I control the switches from my shack. They are mounted on a piece of
plexiglas sitting vertical in a window. It takes less time to throw
the switches than to tune an antenna tuner.

Source record: 111409

Hi Larry,

Looks like a job for RAG-58 coax. Foam insulation in 1 inch square cross section will allow you to run the coax under the sliding window. Another piece in the top of the lower pane will provide temperature insulation. To get past the screen, can you cut a notch in the window sill large enough to pass the coax under the screen?

Good luck.

Bill, W4WNT

Quite true. If the newbie on a budget doesn't want to build something but wants on the air multiband cheap, MFJ sells an L-network random wire tuner for about $40.00.

I am considering the subject antenna for an attic installation in order not to violate the covenants of my housing development. I have read some glowing reports in QST about it, but have not found any local hams with actual experience with this antenna. Anyone out there have one who could enlighten me about the performance? I am primarily interested in working in the 30-15 meter bands at moderate power levels. The peak of my hip roof is approximately 22 feet above ground level.

Message-ID: <3f2d7a76_1@news1.prserv.net>
Source record: 111417

Scott:

The curves for V Beams in the ARRL Antenna Handbook, and apparently also in the engineering texts were derived from a few experimentally determined data points assuming a sinusoidal current on the arms. In the July 1980 IEEE Transactions on Antennas and Propagation, Gary Thiele and Ernie Ekelman published a rigorous NEC analysis of the configuration, including a couple of useful curves. Both the optimum included angle vs. arm length and directivity vs. arm length differ significantly from the previously published curves. So, dig up a copy of IEEE-A&P Trans., Vol. AP-28, No. 4, and look on pp. 588-590 for the full story.

Ian, you need to chop one apart again and look at the construction. The
contact pressure is provided by the wavy washers behind the shoulder. The
rubber washer, which is on the other side of the shoulder, if anything
opposes the contact pressure direction as it 'seals' against the end of the
female cylinder. The best BNCs in the Colonies are manufactured by
Trompeter, and the price shows it.

Hello

> What is the best am indoor loop antenna to buy ?

Why buy, they just cost a lot. Build your own, one like
this works very well and the cost is very small.

http://www.hard-core-dx.com/nordicdx/antenna/loop/1mloop.html

If you want it smaller, I have designed one I can send you a picture
and a drawing of.

Regards Max

You may want to look at my recent article in QEX magazine. The first
part, in the Jul/Aug 2003 issue, describes the design of the loop antenna
proper. The second part, to be published next month (Sep/Oct 2003),
describes the amplifier, remote tuning, and controller.

>
> Regards Max

Yep, Those are a snap to build. The only part he really needs is an old variable cap out of an old radio. The common 365pf variable used in old BC radios will work fine. 500 pf even better. Then it's just a matter of winding a loop on something. It can be anything from a large box, to a 2 ft or so piece of 2-3 inch dia PVC tubing. "broomstick style" I prefer normal larger loops though. You can use the single main loop as is, or you can feed it with a 2nd coupling loop, which is mounted behind the main loop. This will usually improve the balance a bit. I built one on a round 16 inch dia plastic blower housing from an old humidifier. It is mounted on a short mast that fits in a heavy mast holder I have sitting on the floor. If I want to turn it, I just reach over and give it a spin. The main loop is 12 turns, and I use a 2 turn coupling loop. With the cap I have, I can tune from 500 kc to 2000 kc. I design the number of turns around the cap to be used. It's the value that can't be changed. You can tack fixed cap's in parallel with the variable though, if you want to drop lower in freq.
You can also build the main loop only, and use the ferrite antenna in the radio as the coupling loop. But then you have to keep the radio mounted behind the loop, which is a PIA. But that is one way you can try the loop without even making a direct connection. It does have to be tuned though with the cap when you do this. You'll hear it peak up, if it's resonant. I've found a loop very worthwhile on AM-BC. You can null the crud, and dig the signals you want out of the mess. A random wire usually gives you 4 stations at once. MK

All the others had good ideas. But in reality, almost anything will
work those Russian birds. I've used dipoles, GP's etc.
Whatever...Something like a turnstile would have a better
omnidirectional pattern. Those are simple to build. Crossed dipoles
fed 90 degrees out of phase. You can feed the 2nd dipole with a 1/4
wave length of line from the 1st dipole. Keep in mind the VF of the
coax. The line will be shorter than a physical 1/4 wave. Some add
reflectors below the turnstile. I think probably overkill for
RS-15..The VHF side is more critical than the HF. I usually ran 10/15
m. MK

Really, some how or other I got the impression you had to go outside to
change bands. I have some nice open frame DPDT relays that I think would be
great for this. They are more like solenoid actuated knife switches than
what you would normally consider a relay. Actuate one solenoid and the
switch changes. After you deenergize the solenoid the switch stays in the
same state until the other solenoid is energised.

I passed along this info to Dean Straw, N6BV, the ARRL Antenna Book
editor. He replied that since the 19th Edition, he's used EZNEC/4 (an
NEC-4 based program) for generating rhombic and vee beam data. I'd hope
that it would agree closely with the 1980 NEC analysis.

Well, thank you, George - they do say "Learn a little every day"! I've
sawn up several BNC plugs, but never in that particular way.

Even though it's a wavy washer, the fact remains that the spring
eventually weakens (it happens it in C plugs also).

Hm, I assembled about a gazillion BNC connectors in a previous life. They were whatever brand the Air Force bought, and they didn't contain a wavy washer. The pieces were the shell, the tip, and the screw end; and to hold the braid on the inside there were only the rubber washer, a strange-shaped washer, and a flat washer (to go between the screw end and the rubber washer to reduce the friction when tightening). One surface of the strange washer was flat (actually, stepped), and that was where the braid was smashed against the boss inside the shell. The other was tapered in such a way that it would force the rubber washer to expand outward to squeeze tightly against the shell. When disassembling one, we'd often find that the rubber washer would be cut nearly in two. The only pressure on the braid was from the rubber washer via the force of the screw end.

A common mistake was to put the strange washer in upside down, since it just looked right that way, with the braid nicely cascading over a sort of angled surface. When that was done, the washer wasn't properly expanded by the tapered end of the strange washer, and you could easily yank a connector off. When properly assembled, there's no way you can yank one off.

I have a bunch of connectors in my junk box which are essentially the same as I've described, but with a couple of more parts relating to the tip and insulator. I assemble one from time to time when needed and, like their military counterparts, they've been very trouble free.

The window-line loops are outside but the switches are inside. I've
got a chart on the wall that makes changing bands a snap from the
operating position.

2492. 80 m Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-04 13:07:22 UTC
From: whitehat <rpav@suffolk.lib.ny.us>
Message-ID: <MZsXa.792$603.40779@iad-read.news.verio.net>
Source record: 111286

I will be building a center fed 80 m dipole, 62.5 feet each side of center. The ends will be about 23 feet above ground but the center is not supported to it sags to about 18 feet. I will feed it directly with about 25 feet of RG-213 50 ohm coax and connect it to an antenna tuner in the shack that can tune from 50 to 500 ohms.

This should work okay on 80 m, right?

How well will it do on 20 m?

2493. Re: 80 m Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-04 14:26:38 UTC

Source record: 111287

The antenna will work OK. The VSWR may be a little high due to the low height. Minimum height should be in excess of 65 feet and most hams can't get that high!

Working on 20 meters will most likely be difficult without a good tuner.

I discovered that you can eliminate the need for the
phasing cable by tying together an inverted Vee with
a dipole, and self phasing the two antennas. Probably
not as good as two identical antennas if you want perfect
phasing, but I've not figured out a cheaper technique for
obtaining circular polarization with a pair of antennas.

Self phasing--the dipole is adjusted for an impedance of
50-j50 ohms and the inverted vee is adjusted for 50+j50
ohms, so that when combined, the impedance is 50 ohms
and a 90 degree phase shift is obtained.

Source record: 111293

Have you considered a dipole? You don't need height for the end supports if you have space. For instance, 50 feet of rope at the end of the wire will set the end of the diple to 35 feet if the wire& rope are coming down at 45 degrees. This assumes 0 height at the other end of the rope.

Wrap the wire around itself at the insulator, i.e. don't
allow the wire to slide back and forth through the insulator.

> Does it cause any problem to just resolder it.... electrical tape
> it where it frayed thru?

Make sure the solder is used as the electrical connection, not
as the mechanical connection.

Thermal noise in electronic equipment is typically created by the excitation of phonons, which are resonances in conductors caused by the movement of electrons through the quantum well. Phonons are a type of noise in themselves; they are caused by a certain class of electrons colliding with the crystal lattice of conductors (silver, copper, etc.) through which they are being transmitted. Such phonons travel, not at the speed of light, but of sound, and therefore are instantly out of phase with the signal. Shot noise, which is generated by the operation of transistors, is similar in nature to thermal or white noise. Low-frequency (1/f) noise is always present, and increases as an inverse power of the frequency.

The Bybee solution is based on principles derived from quantum mechanics, the study of how electrons behave at the subatomic level.

Mark,
What sort of range of impedance matching would this provide?
How would you switch bands and what voltage/capacitor range
would be required?
I suspect you would have to have several relays to pick up various
points on the oatmeal inductor as well as a rotation method
for the capacitor

Seems like you have something specific in mind that you would put in a box
for safety reasons. Are the specifics shown somewhere for people to copy?

We can totally eliminate all this noise if we simply operate our
equipment at -273 C.

Hello Jacques

> I Can not buil it myself since i know nothing about electronics.

Actual you do not know anything about electronics to build a loop
antenna, just make a wooden frame and wind some copper wire
on it, solder a variable capacitor to the wire and you are well of.

> I havre no choice but to buy such an antenna in Us or Europe
> What is the best product available in the Market ?
> I've heard about Terk or Palomar .

If you will buy some thing, then take a close look here

http://www.wellbrook.uk.com/products.html#LA5030

I think the LA5030 is a good choise, but you will have to pay.

Roy:

Take an unwanted BNC and the biggest pair of diagonal cutters you have. Clip the latching collar off the shell at the rearmost point of the two latching slots. May take a couple of tries on each side depending on the cutters and amount of force you can muster. Inside you will find the components which create the mating pressure, usually including several half washers which immediately fall out. If you have never cut the latching collar off of a BNC, you have never seen that part of the construction, which is hidden inside the knurl. And, yes, all the BNCs the Air Force purchased had the wavy washer inside, or they would not stay latched. You are describing the cable retention hardware, an entirely separate issue.

BTW, after you remove the latching collar, you now have a universal plug which will mate with female BNC, TNC and N. Depending on brand, the retention is iffy, but I find them very useful for quick connect/disconnect applications. Trompeter plugs, with their machined sleeve, are quite good without the latch.

In a time long, long ago, there were no commercial antenna tuners that I can recall. The first commercial tuner I remember was the Johnson Viking. Everyone I knew made their own. You just went to the surplus store, and got a coil and capacitor that looked about right, and tried it. No one owned any equipment to measure them anyway. We never used relays. Maybe a switch, or just change the coil. The ARRL handbook and Antenna Handbooks still have diagrams for antenna tuners. Also the Hints and Kinks manuals, among many others.

Ah. We're talking about two different things. I thought that the subject had come up about securing the braid within the connector. Ian's initial response was along the line of what I've observed. And that's what I was talking about. But you're talking (I think) about what secures the male connector to the female, another issue altogether.

Yes, I've never broken the latching collar off a BNC, so I've never seen the associated components. I fully believe you that there's a wavy washer to apply the pressure.

Richard, they could be mono-reproducers. This was introduced in the 70's as a device that could faithfully take an input signal and reproduce the signal at the output with no distortion, phase shift, and a gain very nearly one. Also, there was no loss up into the MHZ region. You could take two of these remarkable devices and have a Stereo-reproducer.
If you cooled a 1" piece of #12 copper to absolute-zero, you might improve on the mono-reproducer.

Dick, A REAL LONG time ago when I needed my first tuner I bought a
military surplus ARC-5 transmitter for $5 USD and removed the roller
inductor and final plate tuning capacitor. [Actually, I bought 3 ARC-5s:
one for 80, one for 40 both converted to XTAL control, and one for the
tuner and spare 1625s. Nice NOVICE CW rigs.]

Made a real nice L-tuner at 125 watts continuous duty!!

Hmmm .... where are those old ARC-5s when someone needs them??

2518. When antenna tuner won't tune

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-05 00:25:12 UTC
From: gil <gilpi@mindspring.com>
Message-ID: <bgmt7tfdc1@slb3.atl.mindspring.net>
Source record: 111311

I have the MFJ-971 portable tuner that I use with a random wire when all of the sudden I could not load on any bands and the "forward" power reads very low. At first I thought I blew the rig (TS-430) but then when I tried a couple of different rigs ,the same thing happens... high SWR readings and low power, also tried different antennas with the MFJ-971 and got the same results.
Any suggestions before going out and purchasing another tuner? And is it possible to "blow" a tuner, I dont use anything over 50 watts on CW.
Thanks.....gil

I stand corrected! A little bit of web research shows that this would be a venture capitalist's dream. I have to continually remind myself not to overestimate the golden-ear crowd -- after all, the gold-plated 8 ohm characteristic impedance speaker cables sold (and I assume still sell) like hot cakes. The placebo effect is certainly powerful, but it's possible that the "quantum purifiers" might actually do something. Rather than believe that the purveyor is actually selling components whose composition is "classified by the U.S. military", I'd be willing to bet they're some sort of more-or-less off the shelf varistor. That would flavor the music a bit, and anyone who'd just dropped 600 bucks for a pair of them would no doubt find the flavoring to be marvelous. A few minutes with a curve tracer and some web specifications should pin the source down pretty quickly. But I'm not quite 600 bucks curious. . .

Are you sure it is the tuner and not just the meter circuit? Have you tried another SWR meter? Check the diodes in the SWR meter circuit. They can get fried by a nearby lightning strike. Replacement is easy is and cheap.

Oh yes, remove cover first.

Source record: 111317

Gil,
As suggested, check the wiring (encluding the antenna).
If you aren't seeing any output from the '430 (or the other
ones) I'd also check the feed line between radio and tuner
if you didn't enclude that with the 'wiring' above. If
everything seems to be making good contact outside of the
tuner, then it's time to look inside the tuner. Look for
any obvious broken connections, black or burned spots, etc.
Switch contacts are a likely place to find problems, so
give them a good look. If all else fails, you might 'wack'
it between the eyes just for the hell of it, sometimes it
helps.
Can you 'burn out' a tuner with 50 watts? Yes, just
depends on the tuner...
'Doc

whitehat,
Yes, it will work on 80 meters. Don't count on
using it on 20 meters. Depending on the tuner it
may 'tune', but you won't have the 'best' results.
'Doc

I wonder if the meter or the meter circuit got screwed up?
I connected the tuner to an outside SWR/WATT meter and it seems to tune the antenna well....according to the outboard meter while the one on the tuner itself reads high SWR and low power.

For 80 it will work fine for the heights you have to work with. As most always the higher the beter. If you want to work 20 meters or other bands with the same antenna you might want to feed it with open wire or go to an off center fed or (yuck) maybe the g5rv type.

2528. Re: BNC Connector Power Ratings?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-05 03:06:49 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3f2f2010_2@news1.prserv.net>
Source record: 111322

Well, Roy, here is cut and paste from Ian's post:

"All the contact pressure in a BNC derives from the rubber washer inside
the bayonet ring. A good BNC should need quite a hard twist to make the
bayonet click into place... and in old surplus plugs, this springiness
does wear out."

"....rubber washer inside the bayonet ring." sure doesn't sound like cable
retention to me. Sorry for the confusion, I guess.

On the other hand, when the rubber washer deteriorates, the connectors mate
much more easily once, as the female contact is destroyed in the process.

Ian, I suspect that is your failure mode, as I have chopped up some very old
connectors, and the spring washers still seem to retain their shape, while
the rubber is rotten. On the other hand, I have seen some cheapies which
are soft from the manufacturer. I send those back.

You will be a much happier camper if you feed it with 450 ohm ladder line.
You will have no trouble using the antenna anywhere from 80 to 10, and if
the ladder feed is more than 70 feet you will be able to load the dipole on
160. If the feed line is not 70 feet long, you still will be able to use
the antenna on 160, just join the two sides of the feedline together and
treat as a longwire.

I was interested in having a multiband antenna, rather than a dipole for single coverage and don't have room for a fan array.
"Tarmo Tammaru" <t-tammaru@home.com> wrote in message news:rNacnTr035g1ArOiXTWJhg@comcast.com...
Have you considered a dipole? You don't need height for the end supports if you have space. For instance, 50 feet of rope at the end of the wire will set the end of the diple to 35 feet if the wire& rope are coming down at 45 degrees. This assumes 0 height at the other end of the rope.
"Gregory L. Dome" <gldome@livingston.net> wrote in message news:vit1pflugh0s28@corp.supernews.com...
I am considering a sloper antenna. How will attaching it at the low end affect the reception/ transmission? I have a 75' oak for one point 78 ft. from the radio room, but only have a 20' mast outside the radio room. Other suggestions appreciated

> your other question.

RG213 (RG8) with solid polyethylene dielectric is generally rated at
5kV RMS, and RG58 at 1900VRMS. Though I wouldn't recommend the
practice, I know of people who commonly run 25kV DC on RG-58, though
ONLY by extending the ends so it can't arc around the end, and note
that it's for DC, which doesn't cause the problem suggested in the
next sentence like AC or RF does. You should normally worry about
capacitors with layers of some air and some higher-dielectric-constant
dielectric, because the air will have a higher field strength and may
be subject to corona (which generates ozone and destroys plastic
insulations...), but in the case of the coaxial construction the field
is strongest near the small-diameter inner conductor anyway, so the
(presumably small) air gap between the insulated wire and the tubing
is in a place where it shouldn't be a problem.

Cheers,
Tom

Yes, if you're hamfisted enough, you can easily connect a BNC signal lead to an MHV high voltage supply. They're rare compared with BNC, but they do appear at hamfests.

Whoever invented this booby-trap should have been connected to it! As amateurs, we only need to know two things about the MHV series:

1. Plugs and sockets look like a "stretched" BNC.

2. Avoid.

I used to think crimp on connectors were just the lazy mans way of putting on a BNC. After 15 years of using them I have come to believe they are better than the old style. I just removed an old radar system from service whith hundreds of BNC connections. None of the crimp ons were bad, not so for the others. I am sure this was the cause of many of the intermitent problems that had plagued this radar.

You could use a small pulley suspensed by insulated cord, or a length of
some sort of insulated tubing to run the wire through at the insulator so that it
slides on something slick instead of the porcelien insulator.

[SNIP] If you mean the 136 foot 36% off center fed with single wire against ground it's a pretty fair antenna on 80/40/20/10.

> Looking to put one up . Can I work all bands with no tuner like they say ?

[SNIP] Nope! It needs a tuner to work any band!

>
> Thanks for help

[SNIP] There are other antennas that claim to be a 'Windom' but are adaptations of the basic antenna. The original windom introduced in amateur circles in the 1930s is as described above.

All other versions, coax fed, twin lead fed, open wire feeder fed are adaptations.

A simple 'Windom' fed with a single wire and a tuner will work fine. You may need to trim the single wire length to get RF out of the shack.

==========

Jayne,

No you can't.

Who are "they" anyway ? Antenna salesmen ? Old-wives ?

There is NO antenna which will allow high radiating efficiency on all bands without a tuner.

In fact, there is NO antenna which will allow high radiating efficiency on all bands even WITH a tuner, taking radiation pattern into account!

And to complete the depressing story there is no commercial tuner which will cover all bands from 160 to 10 meters.

To work all bands efficiently, in any geographical direction, you need an antenna farm containing at least 3 separate antennas, a reasonable ground radial system, a number of transmission lines, with availability in the shack of 3 different tuners.

However, the original Windom, which must have first been used 65 or 75 years ago, well before it acquired a name from the first person to take the trouble to describe it in a ham magazine, is a good all round performer. It has to be - it's so simple.

The original Windom is a half-wave dipole, resonant at the the design frequency, fed by a single wire transmission line of random length, the line being tapped off-centre into the dipole. Radiation from the single-wire feedline is intentional. Only a moderate sort of ground-radial system is needed. But a tuner is needed to match any particular band to a 50-ohm transmitter. In the olden-days a 50-ohm transmitter was unheard of.

Relatively modern versions of Windoms are bugged by the sales gimmicks of supposedly balanced twin feedlines and baluns which do nothing but degrade efficiency compared with the original simplicity. There is just as much radiation from the off-centre-fed twin feedline. Antenna salesmen don't mention the subject.

For performance of the original Windom, download in a few seconds and run immediate;y program WINDOM2 from website below

OK, let me get this straight....
It's a good thing to make fun and belittle a newbie who is trying to
learn something?
It's the new ham's fault that the current question pool is too easy for
your liking?
No one without experience should become a ham? (not sure how one gains
experience, but hey, I guess that's not important)

Use an antenna analyzer!

At 1/8 wavelength, from either a short or an open, the input impedance
will be purely resistive. The resistive value is the Zo of the line.

- No sash windows here in France ; they open (and close) like doors.
The window size is abt 0.90 * 1.60 (metres), which makes a gross 1.7 wave,
not so far from a 2 wavelenghts closed loop, like a square in a circle...
I suppose I could try to space my croc clips a quarter wave apart ??

Without any RF test equipment, another way to tell is by physical measurement of the dielectric and inner conductor diameters. But you'll need some calipers to do that. If you have piece of marked cable of the same outside diameter and either impedance for comparison, you can easily tell the difference -- for the same outside diameter, 75 ohm cable has a noticeably smaller inner conductor than 50 ohm cable.

A similar thing happened to a friend of mine. He had his
antenna screwed into coax-2 and his switch set on coax-1.
Hint: Looking down on the back of an MFJ tuner, coax-1 is
not on the left.

NO! You can't test it with a VOM. You need a signal with wavelength
[frequency] characteristics.

Someone in your area should have an MFJ 259B. Ask around.

A word to the wise for people who expect to be able to operate from a hotel room.

I recently returned from rainy Arizona back to my home here in sunny Oregon. While in Tucson, I turned on my VX5 to get a weather report from the National Weather Service, and was surprised that I couldn't get the NWS on any of their frequencies from my hotel room, even with the radio against the window. But remembering an experience I had some time back with a rented car's windshield, I opened the window and -- voila -- there was the NWS. It seems that some hotel room windows are now being coated with the same conductive stuff they use on some car windshields. The attenuation, at least at VHF and GPS frequencies, is impressive. Because I think the purpose is blocking UV (and maybe near IR?) to reduce air conditioning loading, I'd expect it to be much more common in hot, sunny climates than elsewhere.

And windows in high-rise hotels often don't open more than a crack, if at all.

Roy Lewallen, W7EL

Bill,
There are a number of variations on the broomstick antenna. They
are all variations on a helically wound antenna (a coil of wire, usually
fairly wide spaced, on a broomstick or dowel). In the absence of any
other antenna they may or may not work well enough to satisfy you, but
you might do just as well or better with a piece of wire strung across
the room or hanging out the window. Transmitting is another case --
but you mentioned the 'receiving antenna'. Hope this helps!

And you put it up as an inverted v? Concrete walls does not absorb nearly as much RF as one might think. If you are between concrete walls what do you look at through your window. In more than 20 years I have found more people that are convinced that they need to spend more money for an antenna. I calculated the length necessary, and cut one myself to be used in my cellar. I was amazed to see that what I had invested an hour in constructing was identical to what I could have purchased for $4.00. (At the time I had people lined up to pay me $50. to $100 an hour for my tax preparation and planning expertise.) Building the antenna was not the smartest use of my resources at the time. In fact my home rolled one did not even look as good.

How far away are the stations you want to receive? If they are anything like local, within 50 miles the antenna should work fine. Not the "T's" you receive when you buy a receiver. The folded dipole the SKU of which is below. I assumed you knew what I meant by Inverted V. The center of the antenna is higher, or lower, than the ends. The ends include an angle of between 90 and 150 degrees. (45 to 75 degrees off of the transmission line) This makes the antenna omni-directional and it will work great.

But don't believe me. Continue to fight with the window frame, or go and spend $40 to $60 on the amplified antennas that are sold, and that DO NOT WORK.

Roy, this brings up a question , and am curious about-- Just what are the differences between EZNEC and EZNEC -4 ? Have had copies of Elnec, thru EZNEC, and you keep doing great job improveing each one, but keep hearing about NEC-4 (as opposed to NEC, and NEC-2), and am curious (no puns intended), as to what are the major advantages of NEC-4 over NEC, and NEC-2 (what ever happened to NEC-3?) Is it worth upgradeing to, or, of interest only to someone doing complex arrays ? I'm sure others would also be interested, as am not in a position to get engineering tomes (am retired), but am curious. Kinda like a teacher that was at Oregon Institute of Technology (last name of "Barber"), who ran a company that built antennas for military planes - turned out a curtain, so if part of hull was shot, the rest of the hull would radiate! Wished I had more oppurtunity when still in K.Falls to pump him, but they cut his teaching position. Guess you the expert to ask, now-- Jim NN7K

2570. Automatic RF noise cancellation and audio noise measurement

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-05 22:12:22 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0308051412.54d4c913@posting.google.com>
Source record: 111364
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna,comp.dsp,sci.electronics.design,sci.electronics

THE BIG QUESTION: How do you measure the audio noise level in a receiver? Does anyone here know of any circuits that show the overall audio noise level?

Let me tell you what this is all about.

SIDE NOTE: Thanks again to those of you who helped me with the SWR/wattmeter project I worked on last semester. This project taught me more about ferrite cores, op amps, and diodes than ANY class possibly could. I learned about stray capacitance and what rails mean. I also learned that not all 1N34A diodes are alike.

In this coming semester, I will be working on an even more ambitious project - an automatic noise canceller for 160m to 10m. It will definitely be a control system, and it may even use DSP. The device will also require a motor for automatically adjusting the controls. The idea is to design and build an automatic version of the Timewave ANC-4 or the MFJ-1025/1026 RF noise cancellers.

The ANC-4 and MFJ-1025/1026 are manual devices. There are automatic noise cancellation devices, but their adjustments are at the audio level rather than the RF level.

The back panel of my device will contain:
1. Connector for the signal antenna
2. Connector for the transceiver
3. Connector for the noise antenna
4. DC power connector

The front panel of my device will contain:
1. Power switch and the obligatory idiot light to show that the power is on
2. 2 audio connectors: one connects to the transceiver, and the other connects to an external speaker
3. Frequency range control for choosing the inductance values, as the proper inductance values in the RF noise cancelling circuit varies with frequency
4. Phase range knob so that the phase shifter can cover all 360 degrees
5. Manual noise phase knob
6. Manual noise gain knob
7. LED display to show the noise level
8. Noise phase adjustment push-button: Pressing this button activates the control system to adjust the phase shift of the noise.
9. Noise gain adjustment button: Pressing this button activates the

control system to adjust the gain of the noise.

Other features:
1. I need to design my automatic noise canceller so that parts won't blow up if I transmit 100W through it. This probably requires some type of automatic bypass circuitry.
2. Transmitted power must not reach the noise antenna (at least not without a great deal of attenuation)
3. It also needs a low insertion loss.
4. A preamplifier would be desirable.

How it would work:
1. You manually turn the phase and gain controls to the minimum settings. (Or I could put in a reset button to do that. No, that would add too much complexity to the circuit.)
2. You select the band using the band inductance switch.
3. You move the phase polarity switch to the negative setting. If the noise cancellation procedure does not work, it probably means the opposite setting is required.
4. Press the noise gain adjustment button. The device adjusts the noise gain until a change in the signal level (or the S meter) is just noted. (Some type of derivative function would come into play.)
5. Press the noise phase adjustment button. The device adjusts the noise phase shift so as to produce a null in the signal level (or the S meter).
6. Steps 4 and 5 could be repeated to make further adjustments. There might be away to activate the control system with just one button.

Does anyone know of circuits that measure audio noise? Making the RF noise canceller automatic requires an audio circuit to monitor the noise level. This noise level needs to be converted into a large DC voltage, which feeds the motors that turn the variable capacitor and potentiometer.

Not necessarily!, there are also "Broomstick " antennas (VHF- UHF type) that are STACKED sections of coax (Co-linears), where the sheath of a 1/2 wave length piece is soldered to the center conductor of the next 1/2 wave piece of coax (and also vice versa), with several of these sections, done, the last section, if memory serves me right, is a 1/4 wave piece of wire, and it is attached to the last 1/2 wave section, shield, and center conductor shorted together!
similar to DB PRODUCTS- Green Hornet, and has a 1/4 wavelength radial for counterpoise.
as info, Jim NN7K

Sure, Short out your rf input to the audio amp, and measure the noise. If you have a noisy output after you short the input, then you have a noisy amp. If you have a noisy audio amp, then you need another design.

Yeh, and that is (if memory serves me correct) PEAK-PEAK voltage (not 2000 volts, but 2000 volts Peak-Peak or 5640 VOLTS !) Even at 100 watt power level, would take one heck of a mismatch to generate that kind of volts! Keep in mind that in good ol' days, that center conductor of RG-8 was used as Power supply feed for lots of AMPS! 3&4 KV, in some of those!

I want to thank all for the input. The problem seems to be in the meter circuit, couple of guys mentioned the diodes could be shot?
There is no sign of anything burned up or broken, right now I'm bypassing the meter and its components and just using the tuner with an outboard SWR/Power meter.
What is the way of telling if the diodes are bad using a voltmeter? And should they be removed before checking or can they be checked while mounted?

Again...thanks, you guys have been great help

Here are some of the claims:

"Bybee Technologies claims that the quantum filtering provided also
speeds up electrons by as much as 50% and in the process selectively
removes undesirable ones, thus purifying the remaining signal."

The review this was taken from (SoundStage!) then goes on to tout the
"damping characteristics" of the wooden box the device is housed in.
I'm curious about whether the reviewer might also happen to write for
the Weekly World News.

Reminds me of the blind man selling pencils on the street corner for
$10,000 apiece. He claimed he only needed to sell one.

Perhaps basic antenna theory needs to be revisited here (?).

A center fed half wave antenna using standard 50 to 70 ohm coax will operate
with a 'reasonable' SWR at the ODD multiples of the fundamental.

Nice and simple.

How would your noise canceller know what is undesirable noise and what is
desirable signal?
The motor driven gizmos are are kind of history, we have parts that can be
controlled by the voltages electronically.

2587. Re: Vee Beam info needed -diff NEC and NEC-4 ?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-05 23:53:14 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vj0grahq7anobc@corp.supernews.com>
Source record: 111231

There are two major differences between EZNEC and EZNEC/4. The first is that EZNEC/4 is one of the two EZNEC pro programs, the other being EZNEC-M. These programs are intended for professional use (although some amateurs have bought them) and cost several times as much as the standard version of EZNEC. The added features of the pro versions are 10,000 segment capability, the ability to read and write description files in NEC format, ground wave analysis, automated rectangular wire grid creation, and a way to do advanced replication, rotation, and translation of groups of wires. EZNEC-M is identical to EZNEC/4 except that EZNEC-M only has an NEC-2 calculating engine, while EZNEC/4 gives you the choice of NEC-2 or NEC-4. And the availability of an NEC-4 calculating engine is the second difference between EZNEC and EZNEC/4, since EZNEC has only NEC-2.

The most striking advantage of NEC-4 over NEC-2 is that it allows the modeling of buried conductors. It also is relatively free of the error NEC-2 creates when modeling connected wires of dissimilar diameters, and will hold up better at the edges of calculation capability. For example, it'll handle loops which are a bit smaller than the smallest that NEC-2 can manage. For most models above ground, though, NEC-2 and NEC-4 will give you virtually identical results.

NEC-4 has some additional capabilites which I haven't yet implemented in EZNEC/4. These include the ability to include the effect of wire insulation, and the ability to define the conductivity and permittivity of the primary medium (fixed at free space for NEC-2). It also does some checking of the geometry for errors such as overlapping or crossing wires. EZNEC/4 does have it run these checks.

NEC-2 is public domain software -- anyone can get it and use it for any purpose, free. It's on the Web as both source code and compiled for a number of platforms. But NEC-4 is copyrighted by the University of California, and is not free. Any U.S. citizen can buy it for use within the U.S. I believe the cost is still $850, although there's a discount for universities, and some military and defense groups can get it free. I sell EZNEC/4, which includes an NEC-4 calculating engine, only to people and organizations whom I've confirmed have a valid NEC-4 license, via confirmation from the issuing agency. (You don't need to have NEC-4 in order to run EZNEC/4, but you must have purchased it before I'll sell EZNEC/4 to you.) EZNEC/4 is $600 on top of the $850 NEC-4 fee, so no, an upgrade from EZNEC isn't a viable choice for the vast majority of hobby users.

NEC-3 was a forerunner of NEC-4, and was sort of a first attempt at implementing NEC-4's advanced features. It had a number of shortcomings

which were fixed in NEC-4. NEC-4 wasn't available to the public for a
number of years, and NEC-3 was never made available to the public.

If anyone is seriously interested in purchasing NEC-4, drop me an email
and I'll be glad to tell you whom to contact.

Hi Jim,

How close is anything to your flesh when you are holding it? Are you
still holding it, if it were 2 times further away?

73's

Allow me to infuse a different idea. Think about noise as a fairly broadband phenomenon. The same atmospheric noise that you hear on 21.500 Mhz will also be heard on 21.510 Mhz. Consider the possibility of biulding two identical receivers, the main receiver tuned to the desired reception frequency, the other tuned just a few Khz away, but out of the received signal's bandwidth. Then, you detect the noise on the second receiver, invert it, and sum it into the first receiver's signal chain. This concept is used in ultra-low noise, high sensitivity deep space receivers to almost

totally eliminate noise in the received signal.

Now, as to your concern to keep 100W of RF from blowing up your noise canceller. That's what antenna changeover relays are for. They normally connect the antenna to the receiver, but when the transmitter is keyed up, the relay connects the antenna to the transmitter output, and disconnects it from the receiver. Simple, but effective, and has been used for many many years in amateur as well as commercial radio equipment.

With a soldering iron [low wattage] lift one lead of each diode.

A multimeter should read high resistance one way [> 1 megohm] and low
resistance the other way [~<100 ohms +/-].

If it reads low both ways it is shorted; if it reads high both ways it
is open.

2592. Poor vertical performance on metal sheet roof - comments?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-06 00:59:29 UTC
From: kiddi@marel.is
Message-ID: <b7cca008.0308051659.20aa99f7@posting.google.com>
Source record: 111236

I just finished putting up a 6m long aluminum tube for a vertical for 10/15/20m. Its length is just over 1/4 wavelength on 20m and just under 5/8 wavelengths on 10m. The vertical is located at the apex (8m above ground) of a sheet metal roof top, that slopes approx. 30 degrees down to all sides from the vertical. I use use the roof metal as a counterpoise and feed the vertical with an autotuner at the base. A coax runs 6m (18ft) from the autotuner, down through an attic window and to my TX.

Now, simulations (EZNEC 3.0) and common wisdom predict a fairly good performance for this antenna. Not so. When the tuner is set for 1:1 VSWR the RX signals from the vertical on 15m are consistently 4 S-units below a 20m (60ft) long sloper at the corner of the house. I use this sloper for 160m and 80m. When going to the 20m band the vertical is about 8 S-units below the sloper. Even more irritating, the vertical is constantly outperformed by a leftover horizontal wire, approx. 6m long, lifted only 1m (3ft) above the roof.

Switching to the vertical from either wire antenna the background noise and signals drop noticably. This led me to check out the tuner, the feedline, connections, but all seems to be fine. The bottom line appears to be that the vertical is simply a much poorer antenna than either of the wires I have up already - contrary to the theory and conventional wisdom.

Any comments, anyone, before I remove the vertical and turn to another design?

Kristinn
Can you get on the roof with an antenna analyzer and see what the vertical
looks like to the tuner?
Are you certain the roof is electrically continuous?

Kristinn,

I'd try measuring SWR and impedance at the base of the antenna and also ensure that connections to the roof, particularly between the various sections, all have good cotinuity. There is a chance that there is rust and corrosion between overlapping sections.

73s,

Evan

There's nothing wrong with the theory -- but conventional wisdom often leaves a lot to be desired.

What was the gain difference between the vertical and sloper that EZNEC predicts at the elevation angles you're using for communication?

Have you ever connected a dummy load and wattmeter to the output of the autotuner and measured its loss? Of course, its loss can vary a great deal depending on the load impedance, but the vertical's impedance shouldn't be too wild on 20 meters, so the 50 ohm loss figure is probably in the ballpark.

Is your roof a single piece of metal, or is it made of several sheets connected by rusty joints and gaps? If the latter, did you attempt to include this in your model?

Again, there's nothing wrong with the theory. Most models are capable of giving very accurate results -- but the results refelect the performance of the model. If the model doesn't accurately represent the real antenna, then the modeling results won't either.

Date: 2003-08-06 01:30:37 UTC
From: richardharrison@webtv.net
Message-ID: <1174-3F305A3D-142@storefull-2318.public.lawson.webtv.net>
Source record: 111244

F5LCI wrote:
"The window size is abt 0.90 x 1.60 metres---."

The wavelength is near 3 metres at 100 MHz. So, the long dimension of the window is slightly more than 1/2-WL. It can be considered (2) short-circuited stubs back-to-back. At the low frequency end of the band, the stubs may be near 1/4-wave and the antenna will be resonant.

Feed the window frame across its narrow (0.90 metres) dimension in the centre of its 1.60m length.

The frame may be shorted acress its top and bottom to resonate the loop (2 stubs) at higher frequencies for more response.

Kraus advises not to expect an efficient antenna made this way because it has too little conducting materiel unless the frame is substantially fattened. Plenty of folded dipoles and unipoles do very well without a lot of conducting material. The difference must be in the feed arrangement.

But, the application is for receiving, and you don`t usually need efficiency, just good signal-to-noise ratio for success.

The window frame is there for a trial. With clips and feedline it can be tried.

F5LCI can crank or swing his "loop" away from its closed position to see if there`s any directional advantage. It is surrounded by conducting materials which often cause directionality, intended or not.

Best regards, Richard Harrison, KB5WZI

2597. Re: Automatic RF noise cancellation and audio noise measurement

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-06 01:37:39 UTC

There are numerous sources of noise at the input to a receiver:

1) Background HF noise that exhibits a 1/f rolloff characteristic. This has seasonal and diurnal variations.

2) Atmospheric noise caused by local or near local weather. Remember there are 10,000 thunderstorms in the world at any time.

3) Solar flare noise. During an solar X-ray event the HF noise, #1, can increase by over 60 dB for short periods of time.

4) Local line interference noise.

5) In the future, BPL noise.

6) I'm sure there are other noise sources such as defective insulators on power lines. ;-)

The ANC-4 and MFJ 1025/1026 ONLY operate on #4.

So, your first task is to become familiar with the spectral characteristics of each so you can design a basic filtering circuit for the undesired noise source. My ANC-4 does not respond to the 1/f HF solar noise sources, atmospheric induced noise or solar flare noise.

Weather induced noise contains frequency components that are in the audio passband, you can hear lightning induced static crashes in your SSB/AM radio. How will you discriminate between desired audio and static audio?

Solar flare noise sounds like a slowly rising rushing hiss in the receiver. It has a slow rise time generally in the range of tens of seconds to minutes. It is broadbanded and will easily over ride any low level desired signal. The noise to signal, NOT signal to noise, ratio can easily exceed 40 dB making detection almost impossible. These characteristics are proportional to the intensity of the solar flux and also the wavelength of the solar flux. Detecting desired signals in this environment is extraordinarily difficult.

Manmade noise, these are processed by the ANC-4 and MFJ units, contains basically repetitive waveforms from TVs, VCRs, Remotes, Routers, Computers, etc.

A design approach would be to use digital filtering and a series of Kalman filters [digital filter algorithms], assuming they are available to the general public. The Kalman filters would be tailored to the spectral content of the noise source you are attempting to cancel. A

second design approach would be a fast Fourier transform that discriminates N/S from S/N. You want to keep the noise OUT of the FIRST RF STAGE to avoid pumping the AGC and getting false signals. For HF digital filtering this will require a very fast processor [possibly GHz range]

How to measure the AF noise from a receiver? I'd start by looking into a Bolometer circuit with AC coupling. This would give a pseudo RMS reading that could be used as a reference for a series of servo based op-amps to control your gain and phase circuits.

Depending on how far you want to pursue the science it could be a very interesting project.

With a statement of principles it is YOUR Project, NOT the project for the members of this list. So, go and have fun!

Deacon Dave, W1MCE

Jason:

Very similar to what you are describing is popularly known as a "Noise Blanker" Motorola introduced their design for mobile radios in 1959 as an "Extender" In the same time frame, Collins offered a model for the S-Line and KWM-2. I designed a tube model for GE's Progress Line radios, and I forget who designed the solid state version. The concept has been described in numerous places, so do a bibliographic search of Engineering Index, or Scientific Abstracts, or whatever that school has access to. You also need to familiarize yourself with the concepts involved in noise balanced squelch, which was patented by Motorola back in the late 30s or early 40s. It will tell you how to do the audio noise level measurement meaningfully and apply it usefully.

First I would check the coax and tuner performance, make sure you have no bad connections.
When comparing signals against other antennas, keep in mind that vertical is better performer at low angles - DX. Try the comparison on DX signals rather than Eu and high angle propagation. You could esay see 20 dB differences, but check at the beginning of openings to DX areas and see how they compare.

.....snip.....

The Motorola "Extender" and subsequent NB developments are based on the
"Lamb Noise Silencer", patented (AFAIK) in 1937 and, ...with the
intervening war years, the patent expired shortly before the Motorola
product was introduced.

Kristinn Andersen wrote:
"I use the roof metal as a counterpoise and feed the vertical with an autotuner at the base."

Power fed to an antenna divides between two resistances, effectively in series, radiation resistance and loss resistance. Totals of both resistances are affected by both the vertical radiator and the counterpoise.

First, good conductive connections are a universal requirement which is most severe the closer a connection is to the feedpoint as the current density is highest there. Recall that current flows mostly on the surface.

If the counterpoise is lossy, it would be better to hide it from displacement current with the vertical radiator by using elevated radials. Many radials are required to hide the surface below if the spacibg between the radials and the surface below is small. If the distance is large, only a few radials are required. The radials capture the antenna current and keep it away from lossy surfaces.

Excellent advice from George. Motorola`s Extender usually included a switch on the radio control head to enable or defeat Extender operation. The only reason I can think of to defeat Extender operation is to demonstrate its effectiveness, which can be compelling.

The Extender works early and often to put a hole in the radio`s response before adverse effects are generated within. The holes rarely detract significantly from the signal.

Also look for Motorola TEK 21 Pulse Generator instructions. It is a hand-held, battery-operated, zener diode noise maker used to optimize Extender performance in the radio. The TEK 21 saves overheating a car engine just to make ignition noise pulses to obliterate while tweaking the Extender circuit and the the radio`s response.

I spent considerable time and effort erecting a 33ft vertical 40m
antenna with 8 elevated radials at 20ft. Average signal strengths were
about 2 S-units below a dipole and the noise level was about 2 S-units
higher than the dipole. At my QTH, it was a dog.

As a matter of interest, I just did an A/B comparison between
my 80m dipole and my 20m rotatable dipole. The guy in CA
couldn't tell any difference in transmitted signal levels
and I couldn't tell any difference in received signal levels.
In other words, in four directions, my 130ft dipole works
just as well on 20m as my resonant 20m rotatable dipole.

Kristinn,

Before you decide to remove it, I would see if it can be made to resonate on 20 meters by itself. Ditch the tuner, and see how it performs. As somebody suggested, see what it does with a ZL or VK, or even W6. I never had any luck with 20m verticals myself, but talked to an G station on 20 SSB a few days ago who was using one; sounded fine.

BTW, here is an odd one. I once had a 40 meter vertical with the feedpoint at about 30 feet and 4 radials, sloping down at about 45 deg. At the same time I had a 40m dipole at about 50 feet. I made tests with two groups of hams. The one group was about 400 miles away, the other group about 1100 miles. Without exception, in each group people with verticals preferred my vertical, and people with horizontal antennas preferred my dipole. Yes, I know all about polarization not being important for a skywave signal.

Hi Jason:

I think the "signal antenna" and "noise antenna" are both just antennas. I can't see how you can make an antenna that only hears noise and another that hears the same noise and signal. If that's the case then by adjusting the relative phase and amplitude of the two "antennas" what you are doing is changing the antenna pattern. This will improve the overall s/n if there is a source of noise that's coming form some direction more than from everywhere.

In "Beam and null switch step steerable antenna system" U.S. patent <http://www.delphion.com/> 4,063,250 <http://www.delphion.com/details?&pn=US04063250__> Fenwick has an antenna system where the main lobe is steered using time delay beam steering (this is a frequency independent version of a phased array) and in addition can steer a null independent of the main lobe. He used mechanical relays and coax line, but a more modern version could use PIN diodes and a computer to try all the possible main and null lobe possibilities and use the best ones.

To measure the sensivity of an AM receiver you measure the RMS audio output voltage with a signal present and without a signal present. For a more detailed look at the noise you need a spectrum analyzer, like the HP-Agilent 4395A that can make true RMS noise measurements, see: http://www.pacificsites.com/~brooke/4395A.shtml

Have Fun,

Brooke Clarke, N6GCE

Hi Reg,
the antenna at http://www.qsl.net/w5dxp/notuner.htm should cover all
bands except the topband without a device called "a tuner". Of course
it has a tuner of its sort - a set of switchable pieces of twinlead.

Also, be aware that the "Extender" is somewhat different from the typical noise blanker (at least in RCA units), in that these actually have a SEPERATE reciever, that can be tuned to a nearby (but not necessarly the same frequency) that you are trying to eliminate noise on. The output of this is used to control a preamp on the frequency that you are operateing on. This has a major advantage over the typical noise blanker, in that , a strong nearby signal won't overload the extender , if it is aligned 2, or 3 megs away from the frequency range you want to operate (unlike in a transciever, which operats at the IF frequency). As a side note, these make great noise blankers for 6 meters, and are virtually overload proof. Been there, done that! Jim NN7K

- Tnx fer the answer.
As I said earlier I'm in a concrete building facing very close other ones : It is as if I am down a well...
Another problem is the hash generated by the nearby computer/screen : The s-meter does not tell all the truth. That's why I attached an external whip to the window : less noise, and why I want to use the window frame...
The xmitter, powerfull, is only two miles away but hidden by two hills : really, I am in a well !
More complicated, and hard to understand : I get a far better signal when rain is falling.

So far, I have never bought any antenna, only wire. (In another location, I had previously a nice setup on top-band as reported in RadCom abt 10 yrs ago).
I agree with you about amplified antennas.
Best regards,

Richard,
Thanks a lot for your answer.
I'll continue to walk my clips the way you say. However the computer screen is just under the window and generates a lot of hash : some feedpoints I tried were very poor on that point of view ! Maybe the feedline needs ferrite sleeves ?
Due to the concrete/iron environment, I wonder if my window frame could not be better considered as a slot antenna.
Best regards,

I think this would probably be the best solution. The size of the roof
is not mentioned, and is fairly important to consider. The problem
with using a random size roof as a radial system for a ground plane is
you have no guarantee that the roof will present a low impedance for
any certain band. If the roof is appx a 1/2 wave out from the center,
it's about like using a 20m 1/4 GP, but using radials 1/2 wave long.
Being the radials "or roof" show a high impedance, they are fairly
useless.
Also, I suspect excess loss if the noise and signals drop compared to
any other antenna. If the coax is not bad, old or waterlogged, or thin
stuff like rg-58, then I'd suspect excess loss in the autotuner. I
would also suspect the most loss to be when the antenna is used as an
appx 1/2 wave being the feedpoint will be a fairly high impedance. For
just 20m use, I bet if they added 3 or 4 elevated 1/4 wave radials,
and dropped the autotuner, the antenna would perk up quite a bit.
But this still leaves the problem of reducing loss on the other bands.
The radials/roof need to show a low impedance on any other band used.
1/4 wave and 3/4 wave, etc will work. 1/2 waves won't. IE:, a set of
40m radials could probably be used on 15m ok. They won't be any good
on 20m.
16 ft radials are going to be useless on 10m. I missed if the radiator
is multiband or not...Probably the best 20-10 option would be to
switch to a 1/2 wave antenna like an old R3-R7 etc, and not rely on
radials or a ground plane at all. I haven't even covered the actual
roof connections, as it's already been mentioned. If you add resonant
radials any decent distance from the roof, the roof will become a non
issue. Providing you use enough of them, that is...At that height , 3
or 4 should be good enough if they stay at least 2-3 ft away from
metal. Farther off the roof would be even better better. You might
have to tweak the radial length for coupling effects from the roof,
but once they are tuned, they should work. I consider tin roof
verticals more akin to a ground plane, than I do say to a large mobile
without wheels . :/ MK

Out of curiosity, just how much loss do you think "thin stuff like
RG-58", say 50 feet of it, has on 20 meters?

Hi Jason

Theres a whole lot of unworkable ideas on this thread. I shouldnt rush in without reading up well first.

I'll just address a couple of Dave's ideas.

Dave Shrader <david.shrader@comcast.net> wrote

> Weather induced noise contains frequency components that are in the
> audio passband, you can hear lightning induced static crashes in your
> SSB/AM radio. How will you discriminate between desired audio and static
> audio?

Lot of work was done on this in the 30s, the cnoclusion was they couldnt. However you can if you use the standard 405-line TV noise reduction method. Basically detect brief signals that are greater in amplitude than your wanted a.f., and zero or reduce the af output during that time.

> A design approach would be to use digital filtering and a series of

> RF STAGE to avoid pumping the AGC and getting false signals.

I dont see how you can manipulate signals that havent even reached the first rf amp. You cant even read them as theyre microvolts. Putting them thru any kind of digital filter - you work it out.

Jason your idea of mixing different noise sources is also a non runner. Sorry, but youve got to consider _exactly_ what is in those noise sources and how they differ. It will soon become apparent that by the time you add them youve got 2 different things. The noise f distribution might be the same, but the noise signal will be quite different.

Regards, NT

Hello Ivan,

I am familiar with Cecil's binary-switched variable-length feedline. We are friends and I hope to keep things that way. ;o)

In terms of expectations, quite correctly you say "*should* cover all bands" rather than "*will* cover all bands". Actually it doesn't cover (tune) any band.

As a fundamental principle every tuner must have at least two variable components because it has to match Z = R+jX which also contains two variables. In more practical terms a tuner must have at least two knobs, for example, one to vary L and another to vary C.

So it is impossible (or at least extrememly inconvenient) for a transmission line to behave as a tuner because only its length can be changed. Unless, of course, Cecil can invent a way of varying its impedance Zo between, say, 100 and 600 ohms.

But bearing in mind Cecil's primary objective in using a 'tuner' is to provide a load which will keep the transmitter happy, without regard to SWR on the variable-length feedline, his arrangement is successful. It is necessary only for the transmitter to be happy provided its load indicator has a reading which does not exceed much above 1.5 to 1. (SWR).

Whether or not the station operator is happy using a tuner with one of the knobs missing is another matter.

The behaviour/performance of Cecil's 'tuner' can be very accurately modelled using program DIPOLE3. Download in a few seconds from website below. Just vary frequency or line length and watch the line input impedance.

The most important reduction in radio "static" was made by Edwin Howard Armstrong in 1933 when he invented the FM broadcasting system. FM detection can be made very non-responsive to most disturbances, including variations in signal strength. FM proved its value in WW-2 communications and in broadcasting after the first receivers became available in 1939.

When the window is closed, its "balance" may be better, or it could be worse.

Coax could be your bon ami in eliminating the computer display noise if used with FM/TV baluns. Ground the shield to the radio. Ferrite sleeves around the coax may reduce transport of the interference on the exterior of the shield to the radio.

Wasn't this the basis of the TNS?

If so, it worked on impulse noise above the slow AGC level.

The ANC-4 doesn't even let the noise into the first RF stage!!

2628. Distance to Link Coupling in a Loop Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-06 12:59:37 UTC
From: Al <aburzynski@swri.nojunk.edu>
Message-ID: <vj1utq55lqu4b7@corp.supernews.com>
Source record: 111172

I have used Reg's fine loop design program rjeloop3 to help me with building a couple of loops. It was a big help. Thank you Reg.

The shielded three-foot diameter loop I built is for receive only. The primary loop is six turns paralleled by a variable capacitor, and the secondary (link loop) is one turn (same diameter) fed to a preamp or directly to the receiver. The band of operation of the loop is about 200kHz to 500kHz (NDB chaser).

One question that is not answered in rjeloop3 is what should be the distance from the output (link) loop to the main loop? The antenna's I built used flat cable for the wiring and one of the turns was the link so the distance was 0.050 inches. In other articles I have read that the Q, gain, and S/N ratio can be varied by varying the distance between the two loops. Approximately what is the distance? Are we talking a small fraction of an inch or 2, 3, or perhaps six inches apart? I would just like a feeler distance to work with. If the distance is to be over one inch, I'm considering building the primary loop in one hoola-hoop form and the secondary loop in a second hoola-hoop then varying the distance between the hoops. Any thoughts on this or is this a waste of time and effort?

All input will be greatly appreciated. Thank you.

Al

Jim, NN7K wrote:
"---that center conductor of RG-8 was used as Power supply for lots of AMPS! 3 and 4 KV in some of those."

Nothing wrong with that if the right RG-8 is used. RMS Max V varies from 600 V to 3700 V (Belden 9914). Peak a-c or d-c max V should be 5232 V for the Belden cable. This is 1.414 X the rms volts. No need to speculate. Coax tables abound. One is found in the ARRL Antenna Book.

Since I developed this antenna, I have upgraded from an IC-706
to an IC-756PRO which has a built-in autotuner which will match most anything
with a 50 ohm SWR of 3:1 or less. So my variable length feedline is ideal for
hams with built-in autotuners who are having trouble matching high SWR's.

EZNEC models mine at +9 dB at a TOA of 32 deg. +6 dB if you ignore TOA.
That is, of course, off the ends of the fixed dipole.

Jason, AG4DG wrote:
"3. Connector for the noise antenna"

Eliminate the noise antenna for simplicity. Signal at the radio can be delayed to allow silent disconnect before noise arrives to upset it. Like noise squelch, representative interference can be sensed outside the receiver passband from a common antenna. But sensing large interfering signal impulses requires more reception independence than does noise squelch reception of background noise. But it doesn`t require separate antennas as does space diversity reception.

Best regards, Richard Harrison, KB5WZI

2636. FME coax adapter for ham use, ratings?

Newsgroup: rec.radio.amateur.antenna

From: kiddi@marel.is
Message-ID: <b7cca008.0308060742.482fe6b1@posting.google.com>
Source record: 111180

Some coax cable dealers have recently been promoting FME connectors as adapters between the coax cable and the connector (BNC or UHF). The concept is neat, kind of plug-and-play, but I have not come across any specifications or testimonies from amateurs about how they perform in our applications. These adapters don't look as rugged as, say, UHF connectors soldered directly to the coax cable. Some questions I have are regarding:

- Power rating (suitable for 100W or KW on HF?)
- Frequency limits (HF should be OK, how about 2m, 70cm, etc.?)
- Immunity to water, corrosion, etc. in outdoor use.

Any comments or experience, anyone?

73 de TF3KX, Kristinn.

I use such an antenna but feed it differently. Mine is 130 ft long and fed with 300-Ohm xmitting twin lead.

The transmission line connects to the balanced output of a MFJ tuner.

Used it on all bands 80 through 6 till I got a 6-m Yagi and a tribander.

It is still a much used antenna, especially on 80, 40, 18, and 24.

On 40 it is a fullwave doublet and has about 1.5 dB gain over a dipole.

I have used it in 160 by shorting the two wires of the twinlead together and feeding it as a Marconi antenna.

I agree with other posters who wud like to see the center a little higher, but a man's gotta do what a man's gotta do!

Have fun, Jack K9CUN

Good point - If I can get a dos or windows system up and running, I'll model it with that magloop4.exe program. Regardless, I'd intended to pull the center conductor back a half inch or so after stripping the cable to the insulator. I actually intend to use rg-58 - smaller, lighter, and can set the outer conductor closer to the center, for (I hope) higher capacitance. I'm now considering mounting the sides of the cap to the hula hoop with the hoop actually split there, so the hoop is stretched and compressed as the capacitance is changed, to avoid tight flexure of conductors or sliding contacts.

My biggest concern is dialectric puncture. I'll be running a maximum of 5W.

==========
Hi Al,
To have a significant effect on operating Q it is necessary to shift the coupling loop away from the main loop by more than about 1/10 of loop diameter. This is mechanically inconvenient and anyway I've forgotten how to calculate the coupling coefficient between the two coils. A more convenient way of varying coupling between main loop and receiver is to place a smaller loop inside the main loop in the same plane. Just like a Magloop transmitting loop. Additional variation can be obtained by rotating the coupling loop relative to the other. It is easier to calculate.

The two loops constitute a transformer. It makes little difference wherabouts the small loop is located inside the large loop. So it can be located near the bottom of the main loop near the tuning capacitor. It is better to have no direct connection between the two loops. It may upset the natural balance between the main loop and its surroundings and ground. One side of the coupling loop is grounded at the receiver end of the line.

If the line is an appreciable fraction of a wavelength (very unlikely) then use an impedance Zo in the same ballpark as the receiver input Z. It hardly matters whether it's coax or very loosely twisted pair.

The transformer has an effective turns ratio of -

N = (N1*D1) / (N2*D2).

N1 = main loop turns.
D1 = main loop diameter.

N2 = coupling loop turns.
D2 = coupling loop diameter.

Which may be very interesting but will not be of the slightest use unless the receiver input resistance is known.

RJELOOP3 calculates the parallel L and C resonant resistance of the main loop. Call this R1. To match this to the receiver input resistance R2, make N = SquareRoot(R1/R2).

When impedance-matched to the main loop the receiver input resistance damps the intrinsic Q of the loop to exactly half of its unloaded value. The received signal is then maximised.

Prefer to use a larger diameter for the coupling loop rather than a larger number of turns.

To maximise operating Q and selectivity match the loop to 1/2 or 1/3 times the receiver's actual input resistance. There will be a few dB loss in signal strength.

None of the foregoing will have any effect on signal to noise ratio except when the signal bandwidth is appreciably smaller than the bandwith accepted by the loop. But it is best to manage channel bandwidth in the IF amplifier.

The natural Q of a good receiving loop at LF and MF is already high enough to spoil the audio quality of broadcast stations.

Regards, Reg, G4FGQ

I need to run the feeder from my dipole (80m) up thro the eaves, thro' the loft-space to the shack at the other side (1st floor) of the house, approx 50'. No other routes feasible. Because of the route, I thought I'd have less problems using coax, BUT from the remarks in the above recent post, will someone kindly comment on viability of 450 ohm twin feeder over such a route?

Many thanks

Hm. And what is the gain of a dipole? Say, one 30 feet off the ground on 20 meters, at an elevation angle of 10 degrees, broadside to the wire? Or in free space, off the end of the wire? Or when mounted vertically, at an elevation angle of 64 degrees? Or 40 feet up, at an elevation angle of 25 degrees, and an azimuth angle 68 degrees from broadside? All the same? All 2.15 dBi? All zero dBd?

Yes, and a fixed dipole doesn't have much gain off the ends compared
to a broadsided rotatable dipole. EZNEC says the maximum gain of my
dipole off the ends is "MAX GAIN = 0.88 dBi". I am extremely pleased
with my rotatable dipole. So much so that another element is just
not worth that extra half an S-unit.

Having two lobes is way different than radiating only in two directions. A dipole radiates very well over a wide range of angles. A dipole's signal is within 3 dB of its maximum value over about 155 degrees of the possible 360, or 43% of the possible azimuth angles. That's not "two directions" -- it's nearly half of all possible directions. The signal is within 6 dB -- a mystical value to a lot of hams for reasons I've never fathomed -- over a span of 215 degrees, or 60% of all possible directions.

So, are more lobes better? Over what fraction of possible angles does your multi-lobed antenna produce gain that's better than that of a dipole? In other words, for a signal coming in from a randomly determined direction, what are the odds that the multi-lobed antenna will produce a better signal than the half wave dipole?

Hint: You can find out by using EZNEC, in well under five minutes.

==========

If necessary just squeeze heavy-duty 450-ohm ladder line wires close together wherever they pass through a small hole. Line holes with a thick plastic film or a pipe to obtain a higher breakdown voltage. Slowly twist the cable every 2 feet between holes and keep it at least 1 or 2 inches away from foreign materials, long metal conductors or otherwise.

If it was possible to do A-B comparisons at HF you would find little difference - equivalent to a few pF change in a tuner capacitor setting and 1/2-turn change in the roller inductor. To be safe stick to 100 or 200 watts unless you wish to test to destruction under worst case, but controlled conditions (eg., very high SWR) just to see what happens. Probably nothing!

At HF a change in impedance Zo over a length of a few inches when passing through one or two holes in timber or brickwork will have a negligible effect on performance. The advantage of a balanced line all the way to the transmitter may be that a tuner can be located in the shack. If an automatic tuner is used then use easier-to-install coax and locate the tuner at the antenna end.

Over a length of 50 or more feet, at 28 MHz, the lower loss in 450-ohm line relative to 50-ohm RG-58 is worth thinking about. At 1.9 MHz forget it.

But it's only a matter of economics, time and labour, and the well-earned satisfaction of having done a good job which works according to plan.

Ideally you point the noise antenna at the noise, and the signal antenna at the signal. In the real world the noise antenna is usually fixed, but might be pointed at something like a power line. In any case, the noise antenna is usually quite low, and you hope it won't pick up much of the desired signal.

BTW, way back when, either Radio Shack or Lafayette sold a CB radio that used a separate noise channel that was tuned to just outside the CB band. No idea how well it worked.

Well, Richard, tho in jest, serves purpose, that even with 30 watts lost on surface of a balun , (or any other surface, for thatr matter), that by doubleing the size of the SURFACE, that it would take something like 4 TIMES as much heat to destroy it. For the same reason that a transistor, in the size of a micron will vaporize with a slight static discharge , doesn't necessarily mean that a POWER transistor will even feel a hickup, if it takes you 30 minutes with a 100 watt soldering iron trying to get solder on the leads! For the same reason , have 50 ohm coaxial resistor that fits in a reducer for rg-174, to a SO-239, that would probably crack, with the heat, and meantime also have a resistor, 1/3 the size, but made to mount on a heat sink, that will dissipate 100 watts all day! (also made as a 50 ohm load-- same devices, but different uses-- Jim

When building a Trap dipole you start by building from the inside out. Lets say you want an dipole for 20 and 40. Cut a twenty meter dipole, hang it up and adjust it for minimum SWR. Then add the traps and balance of the antenna. You will obtain some loading from the coils in the traps so the 40 meter antenna will be somewhat shorter than you would expect. Prune for operation on 40 meters. The problem with traps is that you need a set for each band you want to work. You can't sneak by on the odd multiple halfwave, the traps might be at a bad place on that 20/40 antenna used on 15. I have a great example of that on a trapped dipole I loaded on 12 to try the band out..

I regret the years wasted with coaxial fed dipoles. Life is much easier if you hang as much wire as you can, as high as you can get it, and feed with ladder line. I work all 80 through 10 with a 68' (34' a side) dipole fed with 460 ohm ladder line. For portable use I have 75 feet of AWG#22 speaker wire. 34" is split and forms the doublet, the rest is the transmission line. It is usable from 80 to 10 and works great.

But, it has the same gain as the dipole when both are configured the same for Az and El.

BTW, the gain off the end of a rotatable dipole is the same as the gain off the end of a fixed dipole.

When modeled in EZNEC, I don't see an input for rotatable dipole!!! If the X,Y,Z coordinates are the same then the gain is the same. Rotate both 90 degrees and the gain is still the same.

Trolling tonight is very poor. The Red Sox are playing. I don't know whether to be happy or sad.

Hi Jim,

No, this is incorrect. When discussing power dissipation, it follows a linear relationship to surface area - not square law (you are mixing radius and surface area arguments). Even letting this pass, power dissipation does not even conform to doubling with doubling of surface area. This departure from expectation arises in the increased distance the heat has to travel to find the surface. This is usually found in having too many fins in an effort to maximize that same surface area (and leads to an increase in Thermal Resistance). Further, more fins also diminish heat transfer through convection (again increasing Thermal Resistance). 4 or 5 fins is usually optimal.

Are there any of you out there that are using or have used the Outbacker antennas, especially the Perth Plus. I am getting tired of changing resonators on my hustler whe I am mobile and I don't like the many quirks that the screwdriver antennas have. I would like to hear from you guys before I shoot a bunch of bucks on a piece of gear that may not work that well. The hustler works like gangbusters. I would like to have another antenna that works as well yet like the Outbacker all one has to do is change the tap plug in and go with no more tuning required.
Thanks in advance

Hi Henry,

This will probably be of no help due to the timing. I have a whole range of GR catalogs with specs for all the equipments. The problem is that I live in Michigan from May to Nov, so I'm in Michigan now, but my RF lab and catalogs are in Florida, where I live the remainder of the time. If you are unable to get the info before I go back to Florida I'll get the data to you after I return. Hope you won't have to wait that long to get the data you need.

Good luck,

Walt, W2DU

Thanks for all the help. I have heard rs-15 only one time on my
dipole.
Iam running a IC-706mkiig. and just a 2 meter vertical, and a 10
meter dipole.
I know i need to to some majior work to the antenna farm, but I had a
accident and broke my hip, so on my time off i decided to get back
into ham radio. But it sounds like you all have gave me some good
ideas, and pointed me in the direction i need to go. THANKS

Jim,
If you follow the 'normal' rules for using twin-
lead feed line you shouldn't have any more (or any
less) problems than if you used coax. There is always
the possibility that RF will 'eat up' all the electrical
appliances in your house, but maybe not.
Nothing except your pocket says you can't change feed
lines or antenna if you want. So, try it and see what
happens...

The line from the change-over relay to the receiver should be shorted
when the receiver is disconnected and either short or a half wave, or
else open when the receiver is disconnected and a quarter wave long.

Fred,

Well with the Outbacker for change the tap (and recoil the wire from bottom to desired tap)
as you change bands. IF you are a constant band changer - it will drive you crazy (like your Hustler),
BUT the positive is all you have to change is the tap -- no coils to remember or store in the trunk

My Outbacker is out on the patio and I find it is seasonal of what bands I leave it at

It's an honor to get a response from one of my favorite antenna writers. I hope I don't have to wait that long too! In one of the old format QSTs you wrote that your design for the antennas in one of the spacecraft had a 17 to 1 swr if I recall correctly. I was trying to find that article to show it to one of my friends who spends too m uch time on swr. Do you happen to recall the issue? And I can't find mention of it in either issue of Reflections. BTW I took the 1710 case apart and there's a 50 ohm temination in there and the GR 874 connectors are probably 50 ohm but I don't know how high a frequency they are generally good for, perhaps approaching a GHz, I'm hoping the low end is good for HF. Inside, the unit is beautifully made, they don't make them like that anymore.

Depends on your favorite bands. It's a pretty good antena for 20m-10m.
About 8 dB down from the top bugcatchers and screwdrivers on 75m.

Hi Hank,

The connectors are good to 12GHz. The instrument is probably useful
through HF, and possibly out to 60MHz with some derating.

It's also the same scheme widely used for years in VHF FM mobile receivers.
There is a completly separate receiver that receives the noise which is inverted and
applied out of phase to the signal channel to cancel the noise pulses received through the
receiver. The scheme obviously works much better with pulse type noise.

It's important to protect the both the noise antenna input and the main antenna inputs on the noise canceller from RF - but trying to figure out if you should short or open the receiver input based on the wavelength is a little difficult when the frequency range covers a continuum of multiple octaves. Not to mention the problem with putting a quarter or half wave chunk of feedline between the changeover relay and the receiver input when the wavelength is 160 meters. That technique works well for any single frequency (or very narrow frequency band as a percentage of the center frequency) and is commonly used at VHF frequencies and above with diode and relay switching circuits for the additional isolation it affords.

An important consideration is the voltage on the changeover relay and the components connected to it. The obvious part is the 100 W and 50 Ohm situation, but consider what happens to the voltage when you have a high (SWR for the hams / VSWR for the engineers). Jason, since this is your project, I'll leave you with the research to figure out the potential range of reactive loads with various antennas as well as the calculation of the resultant voltages. Remember a good simulation models the real world, not just a convenient part of it. I will tell you the result if you don' t give this part of your design its due. Think about PCB traces vaporized, capacitors shorted, transistor "fuses", relay housings melted and what we used to call "essence of Allen Bradley" from the burned resistors. It's about the same as a lightning hit or running 1000 watts through a 100 watt unit! This can be a safety issue as well as causing unncessary delay and cost.

One of the other people noted that it was important to do a lot of reading, research and analysis of your own - I'll second that!

If you haven't run across it yet, start with the term "Null Steering".

'nuff said for now,

Randy Gawtry

Has anyone bought/ used/ worked this antenna?
http://www.g3tpw.ukgateway.net/index.html

I have a very small QTH, with not much room for HF antennas, but
with lots of scope for a good bit of TVI to the neighbors, so a
vert may not be the best solution.

The website is a bit sparse on tech details.

Can anyone comment on this one?

Thanks, Ivan. I'm sure they do. I just don't have a working microsoft-based system at the moment. I'm trying to get WINE up and running, but my role as "Mr. Mom" keeps me from any long projects. It took me two weeks to build a simple two-coil mobile HF antenna, just because I can work on it for only a few minutes at a stretch.

One of these days, I'm going to have to move beyond just talking about it and try to build one of these suckers.

Yes, I agree. I have used open wire dipoles and they work great over all bands. But, my problem is constrained by wife and housing subdivision requirements. So my antenna is confined to the attic. I tried to use a short version of the open wire dipole and it is not loading at all and the RFI is everywhere. So I guess traps are my only option at this point. I just never built one before or had experience with coaxial type traps either. Just need to know where to tune the traps for maximum impedance on the band of operation. Your explanation of pruning makes sense.

Thanks for your reply

I had exactly the opposite results. It was 2-3 S units better at low angles of radiation compared to my low dipole. I've heard other experiences like this too. I just wonder if there some part of antenna theory that's missing that could explain why that happens. Murphy's law, blind luck, who knows. 8-)

Interesting antenna but the Hustler will do the same thing. I use 4
resonators on mine all the time and they have a much broader bandwidth.

I noticed the their spec page wasn't much of a spec page. Narrow swr curves
(Adjustable but you have to get out of the car to do so) and a questionable
200 watt handling capabililitiy. (It's hard to tell as there are no photos
only drawings and the coil diameters are hard to judge.)

With the Hustler, the standard resonators (rated at 400 watts and will do
500 with no problem as I have used them with 500 watts) once trimmed from
your center swr will cover the band with no more adjustments. I get 100
watts and acceptable swr with each band. 75 meters I opted for the "super"
resonator as it has a much wider bandwidth.

I have used hamsticks to bugcatchers to screwdirvers to outbacks and have
settled on the Hustler.

For horizontal antennas -- the radiation angle becomes lower as the height
of the antenna increases and vice versa (with caveats)
A layman's explanation at URL:
http://www.signalengineering.com/ultimate/angle_of_radiation.html

Excuse the CB reference -- but it has some nice pictorials.

Those mathematically inclined can model antennas at URL:
http://www.eznec.com/

This looks like a VHF antenna, based on the length of the elements. May QST has a similar idea for ham use on page 33. If the 909 is to be used for SW, a pair of Hamsticks may be adaptable to a nearby SW band, although a loop could be simpler, cheaper and possibly less noise-prone.

Would 4 inch irrigation tubing be self-supporting at the 32-foot length?

The vertically polarized noise in my neighborhood is the real killer
of verticals.

Source record: 111125

In a previous QTH -- wow was this ever true -- the big cross country
hi-tension lines were just behind me and S9++ noise all bands all the time.
When they got wet -- just turned off the radio -- sizzle sizzle -- you could
see a blue arc across the big insulators. Power company washed the
insulators every once and a while and had a low noise environment for about
a month -- then sizzle sizzle again -- clear up into the TV band.

But at my new QTH -- all utilities are below ground and it is fairly quiet.

Not to run out the brag tape -- but my Cushcraft R-7000 vertical using an
AL-80B amp has worked a lot and I mean a lot of DX.
(Brag stats on request -- hi hi)
Radiation seems to be fairly low as it appears to perform better on the long
haul.

Would prefer a beam or dipole at 48 feet -- but not allowed here.
Palm trees hide a vertical very well hi hi.

Hi OM,

I was listening to SW when I read your note above. As a test I put
the receiver against the display tube of my computer and didn't hear a
whisper of noise. The receiver's speaker magnet did affect the tube.
In fact, I run the audio through the computer's sound board to play
over my Hi-Fi speakers (three components to do one job). However, the
antenna is about 50 feet away with ferrites protecting it. I also use
the receiver on FM for stations about 10 miles away. No noise there
either.

You may need to put the ferrites on the computer leads (the source of
the noise rather than at the receiver of the noise).

Randy,

Speaking of the horse's mouth! I am concerned that Jason might have too high an expectation of what the noise canceler can do. See if the below is right.

1. It can cancel out the noise from a single stationary noise source that is received via groundwave, and will in general do nothing for atmospheric noise as you would have on 75m.

2. For an automated adjustment method to work, and keep it within his means and time frame, he will have to tune to a frequency where there is no signal present. He should then be able to retune to a differenr frequency within a few KHz, and still have the nulling.

3. Consistent with 2, the receiver's AGC voltage is as good an indication of noise amplitude as any. In fact, it can't be measured AFTER the AGC, as for instance the audio output.

Probably overkill. If he tops it off with an 8 foot mobile whip, he only need to get to 24 feet. Three 10 foot lengths of telescoping Al tubing would allow for enough overlap.

Source record: 111130

The RFI is probably due to the fact that your antenna is so close to the affected equipment. I used to make the bathroom flourescent light go on with my attic dipole.

A trap design will have its current nodes in different places than a simple dipole, but if it is working, the field strength in the house will be the same.

The ARRL antenna book should show you where to tune the traps.

Alternativly:
If your tuner (via balanced line, NOT coax) would not tune the antenna on multi bands, try making it into a loop. Follow around the house with the largest size you can. Just staple the wire to the rafters. Don't worry if your tuner does not have a balanced output, with the loop it won't make much difference. The "balun" in the tuner would just add losses.

My roof has shingles made from Steel Slag, not gravel. I suspect it has a much different RF charectaristic than the stone shingles do.

Just to add to the confusion........

I'm on a hill in the country.
The 75S-3B S-meter usually rests on zero.
It's quiet.
I have a SteppIR vertical on a fence post.
The fence is 4000 feet long; steel posts.

I also have a resonant 40 meter dipole favoring the South Pacific.
For 20 I have a SteppIR 3 el Yagi at 70 feet over average terrain.

During the day the 40M traffic nets are useless on the vertical.

At 3AM the ZL's and VK's come in great on the vertical and I CAN'T HEAR THEM
on the dipole.

When I can get a word in I check in to the Spiderwebnet mornings on 14.347.
Comparing the vertical and the beam on 20 as the sun comes up while folks
from VT to Brazil talk is fun.
Try stereo; one polarization in one ear, the other in the other ear.

Fascinating.

Hi all,

Picked up a 2nd hand Daiwa CN-410m crossed needle SWR
meter the other day.
I want to re-calabrate it and check it out.
Can anyone help with a circuit diagram or know where I
can get one from?
Maybe the original manual had it in?

Tnx and 73

Looks good to me. I might even try to build one, myself.
In theory, it should work, but I think that there will be a small null
where the ends come together, unless it's just a loop. Let the
"Experts" argue that matter. If you think it will suit your QTH, go
for it.

I have used one at our radio club,
Not a bad aerial - in fact better performance than I though it
would be. it is basically a nest of dipoles bent round to form
a square. the ends DO NOT meet / touch and the feed point
has a balun on it.

Have fun TTFN Martin

I had a chum who built the same thing but for 10 meters only. It worked
well. I have no reason to think it wouldn't work in a multiband version.

Richard:

One of the problems with the first production Extenders was no limit on the
total duration blanking. Since the individual pulse length was fixed, it
was possible to get 100% blanking on a readable signal, with the right noise
pulse length and rate. Motorola figured this out about the same time we
did, and quietly modified the circuitry to limit total blanking percentage.
On the other hand, the salesmen with one noisy spark plug in their demo
vehicles loved the switch. But, that's been 40+ years ago, and the details
are hazy.

==========

What are the dimensions of an "oatmeal tube carton ?

Are they made of plastic or cardboard?

Here on Euro-side, toilet paper tubes and aligator (crocodile) clips have been in vogue for many, many years.

Incidentally, my father, a survivor of the trenches, was probably the last person to make his own variable, air-spaced tuning condensers to be mounted behind ebonite panels. He drilled panel holes in front of the kitchen coal fire with an red-hot iron fire poker. All wiring was done with bare square brass wire. All corners were at angles of exacly 90-degrees. His radios were Works of Art, appropriately illuminated with a pair of bright-emitter valves protruding from the top of the cabinet. Circa 1922-30.

So began my early education.

Reg G4FGQ.

It even works for _on-channel_ jamming TX'ers off in another direction from the desired
signal (cable co's use
the technique). Separate directional antennas are used for the desired and the undesired
signals. The
undesired signal (jammer) is gain adjusted and phase shifted and then summed into the
"main" receiver signal
path at 180 degrees (and equal amplitude) from the same jammer entering into the main
antenna/rx'er path. The
obvious null for the undesired signal occurs. Nulling of the desired signal is highly
improbable given the
directional aspects of the antennas. The sum can occur in the rx'er front end. Yes, this is
signal
processing down at the microvolt level. One problem is tuning drift.

Hello all. I recently bought an Icom IC-38A and a Cushcraft Ringo II ARX-220B antenna. When the previous owner was taking down the antenna, he accidentally snapped one of the radials at the thread. I put the antenna up without the extra piece of coax and the radials and the SWR is just fine. I can even hear a repeater about 50 miles north of me with the antenna only 10 feet off of the ground.

Will I benefit by having the radials? I was thinking of contacting Cushcraft to see what replacement radials would cost.

>
> Alan K4AVQ/ P40AV

Alan,
Since you are going to put an insulator at the bottom I am
assuming that the 32 feet is for the antenna alone.

Crappie fishing pole on E bay/fishing store $25 for 20 foot
telescopic form

Aluminum tape with adhesive backing approx $6 from hardware store.

2 telescopic aluminum tubes from hardware store $17.

One coke bottle from store.

Assemble to length and stick aluminum tape to it end to end,
Rub down to remove air bubbles.

Drink coke.

Place coke bottle into hole and surround with concrete mix.

Place antenna into coke bottle.

I love those coax traps. About 20 years ago, I spent several hours
with a sweep generator and scalar network analyzer building a set
of traps for 40/20/15/10 meters. Then, I spent almost all day putting
up the antenna. The process is basically "put up one section, check
swr, drop antenna, trim antenna, raise it back up, and repeat until
the SWR is acceptable" (typical dipole scenario). Then, however, you
add a set of traps and the next section, and repeat the entire process
for the next lower (in frequency) band. Keep repeating till you have
all bands covered. Got a nice sunburn and a decent antenna out of the
deal.

The traps can be fairly light weight and compact - I used RG-174 and
wound 'em on empty pill bottles. For test equipment, a plain signal
generator and oscilloscope will suffice, or maybe even just a grid-dip
meter.... Heck - I even got so involved with coax traps that I wrote
a computer program to characterize the things and tell me how many
turns of what kind of coax on what size form would be resonant at
my frequency of interest.

Since that time, I've discovered how pointless it was. Like WB3FUP
suggests, just put up as much wire as you can, as high as you can.
Right now, I'm using a 130 foot inverted L, and it works every bit
as good as the trap dipole did (if not better) from 160 through
10 meters - and it was a *lot* easier to put up. The only drawback
is that you gotta have a tuner.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vj6123kftrsuc1@corp.supernews.com>
Source record: 111148

I've built a number of antennas with coax traps made from both RG-174 and RG-58. There are a couple of ways to connect the traps, with one (sort of cross-connecting the ends) giving a more favorable L/C ratio than the other. But after measuring the trap L, C, and Q and doing some EZNEC modeling, I discovered that it's often hard, even with the RG-58 versions, to get low loss on all bands the antenna is intended for. The loss might be low on the band the trap "traps", but relatively high (typically a couple of dB) on a lower band. Or vice-versa, depending on the combination of bands that the antenna is for. It depends on the combination of bands that the antenna is for -- some are ok, some not so good. The fact is that the effective inductor Q of coax traps made with RG-58 or smaller coax is mediocre.

For a lot of applications, a couple of dB is an acceptable trade for the simplicity of coax traps, but for some it's not. If it's not, I'd recommend doing some modeling, or careful comparison to a non-trapped antenna.

One other word of advice is to make sure you weatherproof the traps in a way that prevents any water from getting between the turns. Water between the turns can increase trap loss substantially.

A very large power transformer mounted on a pole at the edge of my
property has a 35 foot ground wire running down the pole about 100 ft
from my vertical. I suspect that is the source of the vertically
polarized noise.

and no horizontal wires attached to it?
Is transformer producing noise? Or bad connections, arcing?
Mabee vertical antenna due to its pattern is "seeing" more noise than your
ladder fed wunderdipole?

I think there is a major misconception that verticals are more sensitive to
noise because the noise is "vertically polarized". Man made, appliance or
otherwise produced noise is "all kinds" polarized. It is the antenna's location
and radiation pattern that determines the amount of noise or S/N pick up.

One thing to keep in mind is that vertically polarized waves can
propagate by ground wave, while horizontally polarized waves can't.

Well... yes and no (I think).

As I understand it, ground-wave / surface-wave propagation occurs for
vertically-polarized signals (or signal components), but not for
horizontally-polarized signals (or components). Even if manmade noise
is polarized in all planes with equal (or randomly distributed)
polarization senses, only the vertically polarized portion of it will
travel via groundwave propagation.

So, I suspect that the noise-proneness of vertical HF antennas
compared to horizontal dipoles, probably results from a "double
whammy". The horizontal antennas aren't exposed to anywhere near as
much energy propagating via groundwave (because horizontally-polarized
noise doesn't travel well in that mode), and they aren't as sensitive
to it because they often have fairly high radiation angles with a
substantial null towards the horizon.

The vertical antennas are hit with more noise energy, and due to their
low radiation angle they're pretty good at picking it up.

Tnx fer info.
Different setup here : the antenna is only 3 to 5 feet over the computer,
which could explain the hash...
I have the same problem at home, where the TR-7 is just behind the CRT.
Ferrite over all leads helps only a little. Last nite I fed the window
frame in the middle and, yes, the S-meter jumped 2 points up !
To avoid hash I had to put the coax away from the screen.
Best regards to all,

It's simple. Cecil did not use enough radials for the low height he
mounted the vertical. Also, he didn't use it to work much long haul or
dx, which is what the vertical is best for. His antenna was just a bit
higher than an 1/8 wave. For an antenna that high to equal a GP at 1/2
wave with 4 radials, he really needed nearly 40-50-60 radials. A 1/2
wave high GP with 4 radials = a 1/4 wave high GP with 8-10 radials = a
1/8 wave high GP with 50-60 radials = a ground mount with 120 radials.
They all have the same appx ground loss. Now look at Cecils GP at a
bit over 1/8 wave and only 8 radials. Thats not much better than a
ground mount with 16-20 radials. No one will ever confuse a vertical
with 120 radials against one with appx 16-20 in the real world. I ran
a 40m GP at 36 ft, which is a bit over a 1/4 wave up. I used only 4
radials, but my antenna was appx equal to a ground mount with about 60
radials. My ground cdx are better than his also, so if anything he
should need more radials than I did. To me, his results are about as
to be expected. Heck, on 40m at night, my mobile vertical antenna will
outdo my home dipole at 42 ft to anyone at least 1000 miles away. I've
tested it many times. And my mobile antenna was a peanut whistle
compared to the full size GP I ran here at the house. To VK, Japan,
EU, etc, my GP would always be 3-4 S units better than my dipole at 36
ft. Heck, I'd give Tokyo a 20 db over 9 window rattling when I ran
that GP and a full KW. My dipole would be lucky to be S 8-9 with the

same power. MK

I made one from an old heavy duty 5/8 CB antenna, which by itself was
appx 19-20 ft tall. I then added inner wall tubing to the lower pieces
to make it stronger, and then added thinner tubing to extend to about
29-30 ft. The last piece to extend to 32 ft was a automotive whip with
a small ball on top. Worked well, and was totally self supporting. I
had it mounted at 36 ft at the base of the antenna.

Tam,

Dave Schrader gave you the right short answers to your questions in a parallel post to this one; however, question number 2 is a bit constraining. Consider the fact that there are some substantial variations of the ANC-4 and MFJ noise cancellers that others have built as well as few that are floating around in my head and, I am certain, a lot of other peoples' heads. Nobody has mentioned these on this thread yet. Also think about the fact that armed with the same information and skill sets, engineers tend to simultaneously invent the same thing about the same time. Jason seems to have a pretty good tool box and a good understanding of how to add tools to it - witness this thead and his last project. So he may figure out a way to completely avoid a situation like the one you describe, maybe even costing less and being quicker to develop! If he cannot for some reason, then the challenge is to figure out a quick and easy way to do something like what you describe. The only problem is finding a different frequency a few kHz away with no signal present - especially on the ham bands! So maybe a little more reaching question is how does he find a better way to null a noise canceller? Of course, having said all that, sometimes the best engineering approach is brute force - do the obvious the way you already understand and get it shipped (or turned in to the instructor)!

Hmmm.... surely the noise will be phase shifted and altered in amplitude by a time-varying transfer function?You will need to estimate this first.

Well, 50 feet of RG-58 has about 3/4 dB loss at 14 MHz. And when it's old. . . I've got RG-58 that's well over 20 years old, and can't measure the difference in loss between it and new cable. If it's damaged, it might create an impedance bump, which you might or might not notice. But that's true of larger diameter cable, too.

I'm bemused to find that today's hams have somehow gotten convinced they all need BIG cable for a BIG signal. Maybe they've been listening to the same ads that sell people on monster audio cables and SUVs. But I sure hate to see this misleading concept being passed along to newcomers. They'll fall for the ads soon enough without help.

I'm just reporting what conditions exist at my QTH. There is approximately
two S-units higher noise on the vertical than on the horizontal. After weeks
of A/B comparisons, there was never a time or signal where the vertical appreciably
beat the horizontal. There were a few times when they were nearly equal. Two extra
S-units of noise is hard to overcome. I really wish the outcome had been different.

I used *twice as much wire* for radials in the vertical as I used for
the entire horizontal antenna. :-) In addition, the top of the vertical
was 15 feet higher than the horizontal and was a lightning rod. In
addition, the RG-213 cost three times as much as ladder-line. Anyone
need a 33 ft aluminum tubing vertical? Come haul it away.

2723. Supporting theory that Antennas "Match" to 377 Ohms (Free space)

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-08 11:21:48 UTC
From: radio913@aol.com
Message-ID: <1d15af91.0308080321.7a75efd@posting.google.com>
Source record: 111168

Hi,

I looked through Albert Shadowitz's "The Electromagnetic Field",
and found on page 554 support for my original statement that antennas
"match" to the impedance of free space (377 Ohms).

I didn't buy the book, but professor Shadowitz did write on this
page about how creating antennas to most efficiently transfer power to
free space is a similar problem to matching a circuits source to its
load. He goes on to make a short comparison between source/load
impedances to an antenna matching to the impedance of free-space.

Food for thought and no doubt, debate.

Slick

Cecil, W5DXP wrote:
"I`m just reporting conditions at my QTH."

Every installation is unique, but horizontal power lines are often long in terms of h-f waves. At a distance, one receives radiation from the wires which tends to make a zero sum. This happens even though the h-f is likely common-mode on the wires.

Every power pole is supposed to be grounded. Radiation induced and other spurious currents in the power lines drains to the earth through this multitude of earth connections. Though the phase of these currents to earth varies in the various ground wires, you are often closer to one than the others. Radiation phase from that particular ground wire is usually not a jumble at a given frequency due to limited height of the pole. Your proximity to one pole often derives from being served with electricity from that pole.

As horizontally polarized signals don`t propagate via ground wave and suffer extreme attenuation due to cross-polarization when sweeping vertical wires, inducing little energy in them, and due to vertically polarized radiation from vertical wires on power poles, vertically polarized radiation is all you get from the poles.

For an Idea of r-f currents in the ground wire on a power pole, explore close to the pole the signals it radiates with a transistor battery operated portable radio. They can be intense.

Best regards, Richard Harrison, KB5WZI

Randy,

Thanks for your response. The obvious thing you would like to do is to have the software be smart enough to distinguish between signal and noise. But then the hardware becomes moot, and you have invented a better DSP noise reduction circuit.

BTW, I am considering getting an ANC4 to get rid of power line noise on 6 meters. Fortunately, the noise is coming from the North, a very seldom used beam heading.

There was/is a picture in the ARRL manual of a self supporting vertical.
They show the tubing supported by ceramic standoffs from the side of a
wooden post, eg an 8 foot fence post buried half way in the ground.

In the Coke bottle version, the pipe does not go into the bottle, rather the
top of the bottle goes into the pipe; you now need 3 guy ropes to keep the
thing upright. I would first fill the bottle with concrete.

You could combinethe two methods to keep the vertical load off the
standoffs. Don't need the guys.

My ANC-4 is sitting on top of the ICOM 746. I have a short piece of coax, 7 to 8 feet, to a doublet with a total length of 8 feet on the floor against an outside wall.

Works Great!

I've used the ANC-4 for almost two years. While in Massachusetts the QTH was 100 meters from the New England Power Grid with three sets of high tension [> 67,000 volts] three phase power lines [nine wires total]. The power lines were generally quite quiet but during summer humidity and/or thunderstorms they would get 'noisy'. The ANC-4 reduced the noise to S1 typical levels.

Here in New Hampshire, my local noise source is the local LAN where the router is four feet from my receiver. Similar results with the ANC-4.

BTW, it was given to me as a gift by W1KSZ who picked it up on e-bay for about $60.00. Thanks many times over, Dick.

True, but at close distances in which we have our man made noise sources, and power lines contributing to conduct arcing, there is not that much of "propagating" going on (almost near field). Our antennas "see" the noise sources in their full "beauty" of "all kinds" polarization. Major factor is the radiation pattern of the vertical (main lobe close to horizon) and its height (lower to ground - "looking" straight at the noise sources).
Snooping with AM radio with ferite antenna can be very revealing in seeing the polarization at particular point. Broadband noise source (spark transmitter) can be very "ingenious" in producing and propagating the arcs over the wires and air.

Back in Toronto I was plagued by 90% of the time with 20 over 9 from HV power line noise. On 160 and 80 m, even from horizontals the "background" noise was around S8. But having vertical whip stuck at the beach at Cape Hatteras, NC, allowed me to hear rare DX at the opening and closing of the bands and getting reports like "only or first NA station" with barefoot TX. Simply amazing. Oh, and background noise is just non existent, S-meter needle sits at ZERO except when static crashes.
One has to consider and select antenna systems based on requirements, geography and noise situation. If local noise masks the signals, then fuggetabout it. Some gadgets like noise cancellers can help in certain situations (single source, phasing) also by positioning nulls in the antenna pattern at the noise source can help, but it is royal pain in the butt especially for the contester. I am willing to travel to no noise territory to enjoy hearing the band breathe.

So, saying that verticals are no good because they pick noise, is like saying that Ferrari is no good to haul manure :-)

Yep,
I tried to question that few moons back, but was "convinced" here that it is not important.
Generally antenna exhibits all kinds of impedances along its length. I was reasoning that antenna having its lowest impedance higher or closer to 377 ohm should have better efficiency in coupling to the space (air). So loops and folded dipoles should be better in that respect. K8CFU et al, when doing experiments with verticals and radials, found that folded monopole measured higher signal levels (over simple monopole) than expected.
Any progress since then?

What keeps the 32' mast from breaking out of the Coke bottle in the
first wind? (I don't think they construct Coke bottles like they did
in the old days with the thick, green glass.)

Dr. Slick wrote:
"---creating antennas to most efficiently transfer power to free space is a similar problem to matching a circuit`s source to its load. (Quote from Shadowitz)"

Reciprocity rules in antennas. Kraus has an Apendix D (Absorbing Materials) to his "Antennas For All Applications".

Kraus says:
"The use of space cloth (Z=377 ohms per square) placed lambda/4 from a reflecting plane was invented by Winfield Salisbury (1) at Harvard Radio Research Laboratory during WW-2 ---." (Shades of stealth)

However, a century of antenna experimentation has not revealed a practical need to especially design an antenna to match its radiation to a resistive 377 ohms.

Most effective radiation occurs when the antenna circuit is matched and has no loss. 100% of the energy accepted is radiated.

Best regards, Richard Harrison, KB5WZI

An antenna's radiating efficiency has nothing whatever to do with the impedance of its feedline, or whether it's matched to it or not.

Now I suppose somebody will drag in the irrelevant matter of SWR on the feedline.

In the real world for the same size wire on HF, a folded dipole should
be slightly more efficient than a dipole because of lower I^2*R losses.

Actually, you brought up the subject. :-) The feedline's power transfer efficiency is just as important as the antenna's radiating efficiency.

2737. calculate mutual inductance of two wires

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-08 16:36:24 UTC
From: jxwang@sympatico.ca
Message-ID: <25029d62.0308080836.b498925@posting.google.com>
Source record: 111081

Hi:

To calculate mutual inductance of two wires, people refer to
the formula in the papaer provided by G. A. Campbell
(Physics Review Vol 5 pp452, 1915, available at
http://prola.aps.org/pdf/PR/v5/i6/p452_1
or send an e-mail to me and I'll send you a copy)

It's a nice piece of work. The book of F. W. Grover
(Inductance Calculation (1962)) used his formula as well.

But I have a question on the case if the common perpendicular
Pp is within one or two wires. They both said the formula
is for 'any' case, but it seems to me it applys only to case
like "/\" (not in same plane). I don't see how to apply it to these cases:

case 1: two wires, one lays over the other, making a 'X', any angle,
not 90 degree, not necessary centered. You raise the top one to a
distance.

case 2: two wires making a 'T' but with any angle, not 90 degree,
not necessary touched. You raise one of the two to a distance.

If you know how to use his formula into above two cases, please
advise me. Thank you in advance.

Jian

The reason they might do that would be concern for the antenna *system*
efficiency and not
just that of the antenna.

Just out of interest but what do you consider to be the low limit of a
" high radiating efficiency" for the HF bands? With a tuner,
without a tuner?

Dave,

Thanks for the info. In my case, the source seems to be a bank of 4 transformers on a pole about 300 feet away. Weirdest thing I had was S9 white noise from about 40 to 55 MHz with about 50% amplitude modulation at around 50 KHz. Turned out to be a 60 amp cartridge fuse in my fuse box about to go bad. I think the 50 KHz was a mechanical resonance in the fuse.

I don't know about the 746, but my 756 has dual watch capability, which lets you listen to two frequencies at the same time. It would be interesting if they would let you vary the phase of the secondary channel..

There are lots of weird noise sources. As a kid in the 40s, I was part of a family visit to an old farm west of Bethlehem Pa., in what was definitely "fringe area" TV reception. The man of the house was telling my father about the strong zig-zag pattern that sometimes showed up on the screen, blanking out the video and often lousing up vertical synch. He wanted to know if the FCC would track down the interference; he thought it was a ham about half a mile away. Just then, the interference started, and right after, his son came downstairs to join us. A little while later, his daughter went upstairs, and the interference cleared when she got to the top. Without saying anything, I went over to the stairway switch and turned it on and off a few times. "On" caused the interference. When we swapped the bulb with one in a floor lamp, the floor lamp caused the same interference. It has been one of my enduring regrets that I didn't ask to keep the bulb. It was probably thrown out.

Cecil, you forgot the efficiency of the PA DC power supply. There's much
more energy wasted there than what's lost in the feeder.

Sort out your power budget. ;o)

My DC power supply is a 12 VDC marine battery charged by a solar
panel. What's the efficiency of free energy? :-)

> Sort out your power budget. ;o)

Actually, I don't much care about the efficiency of the electronics.
60 Hz energy is cheap. I am much more interested in getting the
generated RF into the ï¿½ther.

Hi Bill -

I tried to find the specific antenna you are considering using your links, but I wasn't able to do so with a reasonable amount of effort.

However, there is no doubt at all that a well-designed trap antenna could do a good job for you.

I am rather bemused by the responses you got suggesting a one-size-fits-all ladder-line doublet instead. I'm sure these can be good antennas; but they usually seem to be presented by their advocates as having no draw-backs at all. That would be an incorrect view, as those antennas have their own tradeoffs--just like other antennas.

The biggest tradeoff is the tuner, of course. If you're planning on running power, this is about a $600 +/- item (commercial models), and it takes up space at your operating position. But you're not done when you buy it and find a space for it... you also have to TUNE it every time you make a significant QSY. (I won't mention tuner losses unless someone brings up trap losses.)

I friend of mine took a look at my array of two W9INN trap/fan dipoles (6-band coverage); but he decided that he wanted to go with the ubiquitous 135-foot doublet-plus-tuner. (He bought the tuner from me, which was great... I don't need it!)

When I asked him how he was doing with his new setup, he reported that it gets out fine on 80m and 40m, but is such a pain in the a*s to tune on the higher bands that he doesn't bother with them. (That's just his experience, other users seem to have less trouble.) Oh, and if he ever decides to run power, he'll have to buy a BIGGER tuner, and probably re-sell the low-power tuner he bought from me.

Meanwhile, I'm enjoying six bands, instant QSY, no tuner needed, and I run power when I want to. Because of the loading effects of the traps, my antennas fit in a very compact space... which is all the space I've got. I hear well,and my reports are excellent. Not bad, not bad at all. All I really want that I haven't got is the ability to get these antennas straighter and HIGHER.

Good luck with your selection, and I hope whatever you choose works great for you.

73,

Ed W6LOL

Cec, Good, now we're back on track. But what's the 377 ohms of nothingness to do with a random length of wire which has any impedance you fancy just by connecting to it. Even without making a connection and just using your imagination. Could the person who confidently raised this subject from the dead please give us some clues about calculating the turns ratio. I don't have ready access to the works of Maxwell and there's no mention of it in my 1992 edition of the ARRL Handbook.

And I think my smiley is better than yours!

Well, perhaps I should have said something like

"...no tuner needed, implemented either as the traditional box with
tunable L and C, OR implemented in distributed fashion as a switchable-
length transmission-line transformer, usually including a current balun."

But that would have been a heck of a mouthful; and most of the users
of this antenna type seem to advocate the traditional form of the tuner.

Actually, I rather LIKE the switchable-length transmission line idea.
Could you refresh me on many different lengths do you find you need to
be able to get the SWR below, say, 2:1 at every point in those 8 bands?
(I think we talked about this in an earlier thread, but I don't remember
all the details.) How do you stow the tuning lengths, and how many
physical switches (or plug-ins) are needed? When you do a typical
band change, does "a couple" of switch operations literally mean two,
or several? Any safety issues with the switches if you're running power?

> > Meanwhile, I'm enjoying six bands, instant QSY, no tuner needed, and

I would only add that I found the W9INN dipoles to be extremely easy
to tune, with no troublesome interactions. Also, there is no "messing"

with either a traditional tuner, or switching a tunable transmission-line
transformer.

Tricky,
After all these years you're catching on. What you really meant to say was
that the feedpoint impedance is not the same thing as the radiation
resistance.

'Antenna' impedance' in the present context is not a phrase known to radio
engineering. Please define.

Reg

I don't think I've really promoted the cause of excess loss in thin coax, but it is worse than thick cable. By damaged, I mean waterlogged generally. There are not too many other ways to damage it to make it overly lossy. I've seen some old thin coax that was pretty bad as far as loss. Quite noticable on 10m anyway...Maybe not 20m as much. I do prefer larger coax any day of the week, but thats mainly to reduce the losses when I have a fairly large mismatch. IE: warc band use with tuner, etc. Also less loss on higher freq's. In this case, I only mentioned it in case the tuner ends up not being the problem. The coax needs to at least be considered. But I think the tuner is the likely culprit. MK

Your local power company has it. Generally at their transformer maintenance shop.... I got 2 gallons which will last me a lifetime free. They buy it by the rail tanker and said the cost to figure out what to charge for 1 - 2 gals was more then it was worth <grin>. They use the stuff in transformers. It's highly refined mineral oil and has anti oxidation additives etc. so it's not "just" mineral oil. There are several makers and brand names but the stuff I got is made by Shell and is called Shell Diala (apparently named ala dialectric oil).

Mike, W9WIS

Very true, but that is simply an observation of fact that has nothing
to do with purpose.

>I was
>reasoning that antenna having its lowest impedance higher or closer to 377 ohm

Just by virtue of using a conductor that can support its weight in
suspension (or compression if a vertical); this generally guarantees
little Ohmic loss which is the only source (other than ground) of
degrading efficiency.

>Yuri, K3BU

Hi Yuri,

Like Mike, you are confusing feedpoint Z with radiation Z. For simple
designs like the half wave dipole and the quarter wave monopole, the
two (feedpoint Z and radiation Z) are nearly identical. Fold these
with extra wire, and all you are doing is Z transforming that value to
another value and doing nothing about the inherent loss (which is
trivial in the first place if your antenna is built from a conductor).

The forced debate that an antenna is/is-not an Impedance transformer
seems myopic in the extreme when simple requirements are violated.
Namely, you cannot offer a simple description of any component whose
dimension exceeds a tenth wavelength (and even that is too long for
these "debates"). It is absurd to think of the antenna somehow ending
at the tips of the wire as though alligator clips there would normally

be expected to connect it to the ï¿½ther. This is like thinking a speaker emanates sound only from the fringe ring of the cone. Neither example could be more absurd (but I've no doubt there will be many attempts to shatter that illusion).

An antenna is a transformer (or transducer for those who prefer) which is immersed in a medium, not connected to it at the ends of the wire. There is a continuum of connectivity that is moderated by complex voltage and current relationships that are in turn intertwined with complex field relationships (all being irrevocably related). This complexity does not negate the transformer (or transduction) operation. In fact the statement of the complexity is the answer to the transform.

An antenna is a leaky transmission line. That the spreading of a transmission line transforms its Z is a commonplace of long standing. That a principle requirement be that this transition occur over a long interval (again, the nature of wavelength is central) is also long understood. Combine the spreading, over a long distance, with deliberate intent to leak the "confined" fields is also a principle found in practice. A notable example is found in the V antenna described in other threads, and the venerable Rhombic is another.

Now, to retract those provisos of long distance (wavelength) and simply look at the standard dipole or monopole; it is obvious that they are violated, and yet this is only to the notion of a simple transform. The short transition, leaky, transmission lines simply have a more complex transform - not the absence of a transform. The first obvious evidence is the notable STANDING WAVE found on the short elements in glaring contrast to the bigger designs.

For some reason, many want to dismiss the arguments against standing waves on transmission lines (the circulating currents are lost to the Ohmic resistance of the line) as not being applicable to the radiating (leaky) elements. Such magic. The simple fact of the matter is that these radiating elements are often many, many times larger that the leads that feed them and offer very much less loss for the exhibited SWR. The path to dismissing the concern is less magic than the simple practicality of having more copper.

A visual correlative of these points are illustrated at:
http://home.comcast.net/~kb7qhc/antennas/Fields/index.htm
Where I show not the far field characteristics, but the near field interaction where the transformer operation takes place. The visual element portrays the near fields in terms of Z in relation to that of free space Z (regardless of what "Ohms" is thought to mean for whatever context).

A point in example with a vertical
http://home.comcast.net/~kb7qhc/antennas/Fields/Vertical/index.htm
reveals that fields in the proximity about half way up the radiator are nearly matched to the Z of free space. The complex transformer

has established a locality of no reflection. Likewise, at the base of the same monopole, the local fields are in high turmoil. At a remote distance where the far field characteristics are felt, these two characteristics are washed out to present the standard radiation pattern.

So what does it mean to have high values or low values? If we were to consider the example of the dipole
http://home.comcast.net/~kb7qhc/antennas/Fields/Dipole/index.htm
We would see the monopole turned on its side, and mirrored with the twin radiator. And then we would notice more, like ground (which was part of the monopole but invisibly balanced). One should notice that ground exhibits high SWR regions in its vicinity directly below the feed point of the radiator. A bit of slight of hand here, because ground is not magic either; and is simply another, albeit lossier, radiator. At this wavelength spacing, the fact that there is high SWR in the nearby fields, and that ground is reflective should come at no great surprise.

To extend this observation we need only lift that dipole to half wave to see if ground follows in its wavelength relationships as radiator. It does. The near fields close to ground are obviously different in nature, but what does this have to do with high or low values? Let's slip a conductive ground mat below the dipole. The result is illustrated as a radiator in a virtually calm space of field interaction (and efficiency measurements show a ground screen improves this quality).

The variations of physical structure all obviously impact near fields and present every bit of evidence to the action of transformation (or transduction). There are fields that create localities of low SWR or high SWR and these are immaterial to the argument of reducing the description of an antenna to transformer (or transducer) because the nature of size imposes no "point" which answers where the transform (or transduction) occurs except at the obvious feedpoint.

But I can well imagine there are those who still linger with the question "what significance is there in these Hi/Low SWR values?"

Think back to your experience of driving a hot summer road, where the shimmer ahead of you presented the vision of a blank blue in place of the black asphalt. A common experience of the mirage, or temperature inversion for those less inclined to the mystical explanation. It is tempting to offer this media dislocality to the analogy of lensing the radiation. For an antenna, this would be to the neglect of the same requirement that the lens be much larger than the source however and such is not the case with these smaller local effects. Instead, they could be argued to be atropic aberrations (like a cloudy distorted lens or sheet of glass, to extend the metaphor). As such, the ground mat offers a means to remove some of the clouding (and is demonstrated by an overall increase in radiation - better efficiency).

Hi All,

Jav, this is the best advice you will get for what you asked for,
mineral oil comes in second. Other advice insisting you locate this
"dielectric oil" to the exclusion of other liquids is time lost when
you could be pursuing the Grail or writing the great modern novel.

Oddly enough, water (H2O) is the best coolant (think about filling
your car radiator with ANY oil), but in all practicality the worst
advice. This is because it is an oxidant, and worse with temperature,
it becomes a conductor when it becomes fouled with oxidation
byproducts.

just the standard answer... as long a dipole as you can fit, as high as you
can get it, fed with whatever feedline you have that reaches, with a tuner
to make your radio happy.... works fine, lasts a long time, doesn't cost
much.

Can we assume this discone ins't huge, ie approx 3' tall typical of
VHF/UHF scanner antennas? And can we assume you have vertical rails on
your balcony? If yes to both, a couple 10' pieces of schedule 40 or
schedule 80 PVC pipe will not cost you much. These can be cut to the
desired length and attached to the balcony rails by u-bolts or pipe
clamps, and the discone attached to the PVC with similar bolts or
clamps. Using two pieces of PVC pipe will stablize the antenna and
provide a place for the coax to be taped as it comes into you home.

good luck

I read some of the return messages and I noticed that the message initially openned by saying that many hams still use a long wire and tuner. He comments to say that the long wire is cheap but the tuner is not.
That kinda hit a cord with me because of my antenna experiences. I have been an amateur since 1964, thats not a brag just a comment. Besides using a random wire antenna, I have tried multi-band dipoles, quads, beams, folded dipoles and others. However, I still keep coming back to my old reliable random wire, about 60ish feet and an L network (the coil connecting to the transmitter and the capacitor connecting between the ground and the common connection of the coil and antenna). Though a very simple circuit, it works very well. Recently I put up a 30ish foot random wire and found that it didn't work on 80, using the L network. After some thought, I broke the random wire and inserted a coil. I now gives me a good swr on 80 meters.
I just wanted to defend cheap, but highly functional, antenna couplers and cheap but useful random wires.
Larry ve3fxq
Sorry if I have come accross a little rough sounding.

First, find out if it NEEDS recalibration! Easiest way I know if to place it in forward direction (normal hookup), in series with a BIRD (or other wattmeter). Measure forward, and reverse power on the DIAWA, and compare with the readings from the Bird. then REVERSE the DIAWA, (OUT put from xmitter, INput to the load, and again read. 1), the output meter should read the same power level that the input did originally, 2), same for the Input meter, read as the output (SWR) meter previously did, and 3) All tests should read within 5%-10% of the Bird. If all 3 tests are met, then forget the recalibration bit!

When I first started out, in amateur radio, my antenna was a random wire about 75 feet long. About 15 ish feet was in the basement and the wire went though a hole drill through the window frame of the basement window. My antenna coupler was an L network. My tansmitter was a dx-60 and receiver was a gr-91, for the first 6 months and then a hr-10 for a few years after that. I did quite well with that arrangement.

Tis possible-- reason the ground radials / extra piece of coax was there is because the *(^$%(antenna was poorly designed- didn't decouple the coax from the antenna. Now what did this have to do with the price of tea in China? well, when AEA created the iso-pole, (really a 1/2 wave coaxial antenna, decoupled with 2- 1/4 wavelength cones), and the antenna , down to the end of the first cone (if memory serves me correct) radiated, giving it , it's stated gain. NO RADIATION FROM THE COAX RESULTED (or very little), to distort the verticle patern.
This was demonstrated at a ARRL convention many years ago, in side by side demo, with the CUSHCRAFT. a sampleing loop next to the coax on the ISOPOLE showed NO RADIATION, while the CUSHCRAFT lit a #43 lamp to almost full brilliance (both these on a loop held next to the coax, about 10 feet down the run.) That EXTRA PIECE OF COAX/GROUND RADIALS was cushcrafts answer to eliminate that radiation (and by corolary, recieve distortion) of the antenna pattern! In other words, without it, your coax is radiating (and also acting as a recieve antenna. If you want the TRUE antenna pattern, put those pieces back on -the one busted radial probably doesnt make that much diff, but as a whole, without it will distort the antenna pattern. As info, Jim NN7K

DO NOT USE MOTOR OIL. DO NOT USE TRANSFORMER OIL.

Use MINERAL OIL ONLY. It is fine for 'normal' Amateur radio powerlevels.
However it WILL cook a bit at 1300 watts if you keep it up a while.

You can get it at a standard drug store.

Dan/W4NTI

Source record: 111021

Gee I spent not more than 2 hours with my MFJ259, my MFJ Tuner (I think it cost me 129.95 and is good for 300 watts, which is three times the power I will ever need, and 600 times the power that I used most of the time), and a pencil and paper. I am old fashioned and maintain a log. In the log I have recorded tuner settings for each of the ham bands. (75 and 80 are separate bands) QSY is a matter of referring to log, presetting dials, and changing bands. If I feel the burning need a quick touch up of the capacitor and I am matched. My transceiver, and the DIP unit sit side by side on top of the tuner, so there is no significant footprint problem at the operating position.

You failed to mention the only major drawback to the ladder line fed doublet that I am aware of. It develops some strange lobes as it gets longer. I have heard that the 44' length of the NorCal "Crappie" dipole was chosen as a compromise between 80 meter efficiency and 10 meter lobes. I have been scared of "fan" dipoles for years. I worry that given a reasonable radiator I put enough 7.810 signal on the air to upset the FCC when I was on 3.905. Of course the tuner you seem to refuse to run would help with that somewhat, but I still do not like having the nearly resonate antenna connected to the transmitter any way. I have found out just how far I can talk with a couple of watts (halfway around the world, after that it is shorter going the other way). I never have run an amplifier, there was a time I put 225 plus watts out on 80, and 40 (TR4) but since I got my first ICOM never more than 100, seldom that much. Still worried about harmonics where I have no business radiating, and the FT817 has dramatically demonstrated just how little power is required for a QSO. Amplify the harmonic, and couple it to a nearly resonate antenna, no thank you, I like my license to much, and do not have all that much money for fines laying around the house.

Thanks for the info. The SWR is fine and I was talking to another station on a repeater about 30 miles away with the antenna only 10 feet above the ground. Guess it's at least working somewhat. I'll need to get the antenna higher up if I want to use that extra piece of coax. I was thinking of contacting Cushcraft and asking if I could by a new radial.

Source record: 111023

When I first stated, I found an old roll of fence wire and ran it out the window. It was probably 50 feet long and I brought it right into the shack. I had an old crystal-controlled (7120 Khz and 3740 Khz) homebrew transmitter my dad built and a Realistic DX-100 (bad bandspread). This was in 1982 so better stuff was available, I just didn't have any money (I was 15). My dad had let his license lapse back in the 60's when he was a General. This transmitter was all he had left and the receiver was a Christmas gift. I used it for about two years and worked all around the world (upgraded the receiver after about 6 months).

I have found that to an extent, patience and perseverance (and a good receiver) more than make up for high dollars.

Patrick

Does coax have a shelf life?

I was rummaging around my father's garage the other day and came across a roll of URM43 that I know to be over 20 years old. It looks OK and the copper is shiny. However, can I be confident that it will not have lost any of its electrical or physical properties? I intend to take it on holiday with me soon and don't want it to fail.

Advice please!!

Thanks

as long as it was kept dry and not exposed to excessive heat or chemicals (oil or gasoline in a garage) it should be ok. give it a good flexing and check end to end to be sure the jacket isn't cracked. a quick electrical test is to hook it up to a dummy load, transmit on the highest frequency band you can and measure the power in and out (if you only have one meter you can make two separate measurements). as long as you aren't loosing too much it should be fine.

Source record: 111030

I'll second the advice. I've got plenty of coax well over 20 years old
that still measures the same as new coax.

You can also determine the loss by measuring the input impedance or SWR
of an open or short circuited piece of cable -- the better the SWR, the
higher the loss. Loss in dB = 10 * log[(SWR + 1) / (SWR - 1)].

I've seen just a couple of examples of very old, WWII vintage cable
whose dielectric had gotten brittle and cracked. That would probably
impact the characteristic impedance as well as the maximum
power-handling capability. But I haven't seen anything like that for
more recently manufactured cable -- others may have.

That bulb was probably an old coiled 'Edison' type . They were /are known to
form a tuned circuit resonating in the old TV band 1 (about 48 - 62 MHz)
acting as a TX when power is applied.

I have the 2 meter version and had 2 of the 3 radials snapped off by a wayward tree limb during a big storm. Both broke at the end of the thread. My neighbor was able to re-thread THE OTHER END, and as a bonus, re-threaded the broken off end. The radials may be a little short (by less than an inch), but they still work as well as ever. Also, 36 inch aluminum rods can be purchased at Home Depot for around $4 per rod. These could also be threaded and cut to length.

Just went for a cheap magmount GPS antenna in the end.

I'd recommend:

http://www.lynks.co.uk/antenna.html

They seem very efficient at ordering and dispatch an accept any kind of payment.
You get a real person on email not a robot (even at 2am!!!)

£37.95 (inc. P&P UK only) which seems a fair price for an active 5V magmount
with 3 m of cable and any connector you like. Lots of combined GPS GSM
antennas, but Combined V.H.F (2m) and you have to pay custom built prices (300
plus dollars).

I used drug store mineral oil in my Cantenna. Worked fine for 100
watts, but kind of expensive, buying it by the pint :-)

MFJ sells a gallon of transformer oil, by itself (they also sell their
version of the Cantenna). Check their website.

Hi Mike -

Thank you for your perspective and added comments.

I am well aware of the goofy patterns on the higher bands
exhibited by the one-size-fits-all dipoles; and I assume that
most other hams are also aware of this.

Said patterns do not seem to bother the advocates of this antenna type,
however. And it didn't seem worthwhile to me to get into an un-
provable debate as to whether those patterns are, or are not, a problem.

As for poring over the log and tweaking the knobs when you QSY,
that is certainly your right. But the instant-QSY guy may have bagged
the DX and moved on the next one while you're doing all that.

You may be stuck in a bit of a time warp as regards FCC monitoring--
even if your rig does not have good harmonic performance. As I hear
the CB-type operators polluting our bands with their profanities and
deliberate jamming--every day--I would WELCOME closer scrutiny
by some authority. If I ever get an OO notice (or call from another ham)
complaining about harmonics, then I'll start worrying about harmonics.

As for the joys of QRP, that's really OT for this thread. If you enjoy it,
that's great. Personally, I incline more towards the guys who say
"Life is too short for QRP."

Hi Tom,
From memory I recall that the subreflector is hyberboloid- Y=A/X.
I also recall from real world experience that these can be a nightmare to
align/optimize and one has to deal with significant aperture blockage.
Why would you want to use this system- are the feed/electronics too heavy to
mount out in front as in a prime focus dish?

I don,t fully understand why motor oil should not be used
in a dummy load! I need to make one so I can calibrate
one of my instruments. I intend to use one of the uptodate
gallon paint cans that has a PTFE liner and solder the lid on.
Since we now have the means to use low wattage signals for
tuning up purposes there is obviously no reason to store it
in the shack . So what really is the problem with using
available oil instead of emulating the aproach of industrial
transformers or regurgitating old thoughts ?

From the Google Group Search Engine: For what it is worth

The Handbook (at least my 1990 edition) has some information on this
subject.
In the Station Accessories chapter there are plans to build a couple of
Cantenna type dummy loads. They mention an oil sold by Texaco (if I remember
correctly) for turbine lubrication that is, according to the author, the
same
oil as is used in transformers. They quote the exact product designation.
Apparently, it's sold in minimum 5 gallon quantities and I think it's about
$5 per gallon. If anyone's interested, let me know and I'll look up the
information and pass it along. It's supposed to be PCB-free, also.

The article also cautions against using motor oil for various reasons, among
which is that it attacks the resistor (actually, I think it's the additives
that cause the problem).

Mineral oil from the drugstore works just fine, is easy to get, and is inexpensive. BUT keep the dummy load in a small plastic pail/pan. When it overheats, it vents to the top and then down the sides.

Ran it on EZNEC. Over a "Perfect Ground" 10 feet up it showed a beautiful
Omni pattern on two with 9.87 dbi gain, and on 440 the pattern had some
lack of uniformity in the horizontal pattern but an 11.82 dbi gain. Guess
copper pipe can be "magic". and since bandwidth is directly proportional
to conductor diameter it probably would cover the entire band very nicely.

Wildlife biologists have the problem of squirrels getting into their bird-boxes and they use a product called tanglefoot in a 1 gallon paint can that you trowel onto the post ot tree the squirrels(and raccons) use to make their raids ...Those that fail to ignore this stick sh*t become irrevocably glued where they step

It also is used to make glueboards for rodent trapping by troweling it onto cardboard panels...Try a pest control product supplier

Be wary, that stuff is really STICKY and I don't know YET how to get it off, and I been using it for years

> of effort.

Sorry, my ISP recently ceased operation. You can find the page
originally referenced, at least in the near term, at:

http://users.tellurian.com/jdegood/coaxtrap/

It's simply a six-band trap dipole. The 5 pairs of coaxial-cable traps
provide significant physical shortening, although to fit in an attic
some or all of the outermost (80 meter) portion will probably have to be
run at right angles to the main dipole. The advantages of such a
resonant antenna include a decent match to a coax feedline and no-tune
operation (but over limited bandwidth, a side-effect of the reduced size.)

Another alternative for multi-band operation in a restricted space
situation such as an attic is a physically shortened dipole in
conjunction with a tuner and open wire feedline. For details, see:

http://www.arrl.org/tis/info/HTML/limited_space/limited1.html

> You can also determine the loss by measuring the input impedance or SWR
> of an open or short circuited piece of cable -- the better the SWR, the
> higher the loss. Loss in dB = 10 * log[(SWR + 1) / (SWR - 1)].

==========

The above formula may be correct but it's not of any practical use.

(1) It applies only when SWR is measured by running alongside a slotted line with a voltmeter, stopping to make a note of the voltmeter readings at the max and min points, and then calculating Vmax/Vmin. It is of academic interest and is entirely unrelated to line Zo.

(2) The error in application arises from the confusion caused by the old-wives incorrect assumption that the TLI (Transmitter Loading Indicator) actually measures SWR. It doesn't.

(3) If the ordinary TLI did measure SWR then the measurement would apply only to 50-ohm lines. On any other line, such as old coax when Zo is unknown, the measurement would be meaningless.

(4) If the cable to be checked was really 50 ohms and the so-called SWR meter was standardised on 75 ohms then the measurement would be equally meaningless.

(5) If the shack 50-ohm SWR meter can be relied upon (and most of them can't) then the ONLY information to be gleaned is to measure both the short-circuit and open-circuit SWRs. If they are in the same ball park then the unknown cable is probably not far from 50 ohms.

(6) Line attenuation is a very small quantity. It is the most difficult of all line parameters to measure accurately. The last instrument to choose is the SWR meter in the shack. The most attrocious mechanical damage can be caused over a short length without hardly any effect on attenuation over a longer length. To detect the presence of other than catastrophic cable faults is not possible by attenuation tests. There are far more sensitive ways of detecting and locating faults.

(7) To check an old length of line just test for DC continuity and look at the ends. If all is bright and clean there's nothing wrong with it.

I have traps for the 18AVT/WB.

10 Meter trap

15 Meter trap

20 meter trap

80 Loading coil, with whip assembly top hat plate with four radials.

Whip on 80 Meter is set for the phone band.

NO BASE ASSEMBLY

Have the M-1 tube and interconnecting tubing with clamps.

Use about 3 years and stored. Also have the conductive grease
which I also used on all antenna connections.

Condition is good coils are okay and 80 Meter coil has a
Q of 200 which is correct for this coil.

Interested email. $80 plus postage.

ex: Customer Service Hy-gain and Telex-Hy-gain these are hard to find items.

A friend of mine saw a puddle of water under his rig. Closer examination showed it was coming out of the 9913. I think the flexible version is OK though. Still, I bought LMR400 at work. I use 9913 indoors only.

The ratio of the radiated E-field to H-field has no other choice.
If you stuff EM radiation into free space, the ratio of E-field to
H-field is 376.7 ohms. Zero energy is lost from the EM spectrum when
an electron throws off a photon (until that photon is annihilated).

Hi. I just purchased an FT-100 mobile rig. I want to put it in my 2003 Nissan Xterra. I am thinking of two antennas. One for HF / 6 Meters and the other for the VHF/UHF stuff. I'm trying to keep this as simple as possible, and I'm looking for recommendations. Right now I'm looking at the Outbacker for HF/6. Anyone using that? Any other suggestions? Do you recommend a mobile antenna tuner?
thanks

Only at some distance from the antenna. You can create local E/H ratios
of nearly any value (magnitude and phase).

The near field has a reactive component to the
impedance. But is it true that the real part of
that complex impedance must be 376.7 ohms resistive?

Not at all. For example, the magnitude of of the wave impedance E/H is much lower than 377 ohms very close to a small loop, and much higher than 377 ohms very close to a short dipole. Interestingly, as you move away from a small loop, the magnitude of E/H actually increases to a value greater than 377 ohms, then slowly approaches 377 ohms from the high side as you move even farther away. The opposite happens for a short dipole -- the E/H ratio drops below 377 ohms some distance away (a fraction of a wavelength), then increases to 377 ohms as you go farther yet.

Hi John -

I checked your link... It worked, and the article is excellent!

The antenna described looks very neat, and would be a
fun project for someone who enjoys home-brewing.

For someone preferring a minimum of home-brewing, W9INN
has about eight similar models (SSD series and MDX series),
ranging in length from 46 to 71 feet. I haven't tried them all,
but my experience with his MBD-847 and SSD-021-5 antennas
has been excellent.

About a year later, I read about such a bulb in QST. The author believed that Edison-effect electrons excited a self broad-band resonance in the doubly coiled filament, sustaining oscillation by a mechanism I forget, but that seemed reasonable at the time. Incandescent lamps are filled with low-pressure nitrogen to avoid damage from the Edison effect, and interaction with the gas figured in his explanation. It was that explanation that led me to build an open-air triode. I was surprised as anyone when that worked, and I took it as a confirming instance for the now-forgotten explanation.

Thank you thankyouthankyou! I've been called a crazy liar more than once over that bulb. There was no channel 1 when that incident happened, but I suppose that a small change of geometry could raise the frequency. The explanation in QST had it that the frequency was swept over a fairly large range as the voltage varied during a cycle.

>
==========

Al, I was able to respond in some detail to your query because you gave me a clear idea of your objectives. It was also a topic likely to be of interest to other readers. I do appreciate that many questioners are unable to descibe a problem in terms which people like me (I'm no genius. Neither am I a mind-reader) are unable to understand sufficiently clearly. Furthermore, I have to be aware the enquirer is as likely to be just as unable to understand my reply as I am in understanding him. I have to guess a person's circumstances from an extremely limited amount of 'data'.

If we're not careful a thread continues with further questions, is extended interminably by well-intentioned and other 'do-gooders' and eventually fizzles out with everybody suffering from raised hackles. I mention these aspects of newsgroup info-exchange, or often mis-information exchange, for the benefit of other readers. Everybody has a different motive for joining in.
.....

Just to complete our technical discussion, if program RJELOOP3 does not make itself clear, then if you have N turns on the main loop and one turn closely-coupled turn of the same diameter connected to the receiver, then the Q of the main L-&-C tuned loop is damped with a resistance across it equal to N-squared times the receiver input resistance.

So, if there are 6 turns on the main loop and the receiver input resistance is 1000 ohms (a bipolar transistor) then the equivalent resistance shunting the main loop is 36,000 ohms. If the parallel resistance of the main loop is 100,000 ohms (a typical MF value) then the resulting operating Q of the circuit is reduced to roughly 1/3rd of its intrinsic value. This is over-coupling but may be acceptable.

But if the receiver input resistance is 50 ohms then you will feel obliged to do something about it. As you cannot reduce the number of turns on the coupling coil to less than 1 then, as described in my original reply, there is no alternative but to reduce the diameter of the coupling coil, either a square or circular, and locate it inside the main loop in the same plane. Using 12 or 10 gauge enamelled wire (a better appearance) it will be self-supporting.

Reply not needed. Just make an entry in your notebook. I have volumes A to S. The bookcase shelf is sagging. You are sure to be successful with your

experiments. It is impossible for an experiment to fail. ;o)

From: DOUGLAS SNOWDEN <snowden@peoplepc.com>
Message-ID: <vjblrrdjunf9f4@corp.supernews.com>
Source record: 110997

If one were to use aluminum tubing for the vertical elements on a bobtail curtain what would that do to the bandwidth and lengths of the elements as compared to a all wire curtain? I would like to use 2 inch tubing supported at the bottoms with a wooden post. I guess I might want to put extra insulation on the pipes since there would be a lot of voltage there ...

I hope you're joking, Dan, and that you'd really try to get a
stray dog to your local rescue group or Humane Society.

But if you're NOT joking, I would just advise you not to
try shooting dogs in our neck of the woods.

Don't fool around with the OB. Who wants to get out of the car and switch
taps to change bands? Get the ATAS 120 from Yaesu. For VHF/UHF get a
separate mag mount antenna. The combination will keep you happy.

2829. Length of Coax Affecting Incident Power to Meter?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-10 00:49:36 UTC
From: radio913@aol.com
Message-ID: <1d15af91.0308091649.2f83eed3@posting.google.com>
Source record: 110972

Hey,

I've been getting different readings on my power meter that depend on the length of coax that i use to the meter (into a Cantenna).

This is a push-pull VHF 300 watt transmitter with a coax stub harmonic filter on the output. My digital Daiwa will read about 310 watts incident power using a 4 foot RG-8X jumper coax (from filter to meter), and about 240 watts using a 12 foot section of RG-8X!!?? VSWR stays the same at about 1.4:1 .

There is the old ham wife's tale that you can tune your transmitter for a better match if you adjust the legnth of your coax to the antenna. And from a theoretical point of view, it _should_ be only a tale, because if your antenna is not a perfect 50 Ohms, the length of the coax should still not matter, because the constant VSWR circles around the center of the Smith Chart have just that, the same SWR independant of the wavelengths away from the antenna (assuming 50 Ohm transmission lines are used).

OTOH, the actual series equivalent complex impedance will be alternating from inductive to capacitive, every 1/2 wavelength. So perhaps this will tune/detune the amplifier?

Any non-bullsh** advice/explainations appreciated.

Dr. Slick

With a non-resistive load, the length of the coax and placement of an inexpensive (e.g. non-Bird) meter will cause different readings.

2831. Proposal : SWR meter - TLI

In view of the many years of confusion, misunderstandings, heated arguments, caused amonst radio amateurs by referring to that essential instrument, located between the transmitter output and its tuner/matching network, as an SWR meter, it is proposed its NAME be changed to the TLI.

ie., - the TRANSMITTER LOADING INDICATOR - which it what it actually is.

Reg, G4FGQ.

Stuart,
Most of the other suggestions will probably work just
fine, but I have a suggestion which is much more satisfying.
The first part is the only dificult part, catching the little
buggers. That 'tangle foot' should work pretty slick, though.
Next, visit your local hardware store and buy a 4 oz. ball-pean
hammer. (Light ones are for squirrels and such, the heavier
ones are for bigger game.) Now, when you have one of the little
buggers caught, beat it to death with the hammer. Lot of work,
I know, but much more satisfying than shooting them.
'Doc

PS - An 18 oz. ball-pean hammer is legal for deer here.

2836. Re: GR 1710-P2 ?

The instrument you have goes with a GR1710 vector network analyzer
system, rated 400kHz-500MHz.
It is likely 50 ohms as the 75 ohm versions were clearly marked "75
ohms" all over the place.
RF IN is from the VNA sweeper,
REFLECT OUT is the reflected signal from the device under test,
REFERENCE OUT is the reference signal from the VNA
UNKNOWN is the DUT port.
Just a directional bridge arrangement, but set up for coherent
(vector, phase-referenced) measurements.

I use 5 different lengths in a binary pattern. It's described on my
web page. 0-32 total feet is needed to cover all of 75m.

> (I think we talked about this in an earlier thread, but I don't remember
> all the details.) How do you stow the tuning lengths, and how many
> physical switches (or plug-ins) are needed? When you do a typical

> or several? Any safety issues with the switches if you're running power?

The loops are about six inches apart on the outside of my window. I have
five 4PDT knife switches but I don't bother with the lower two on 75m.
I don't bother with the upper two on 10m. The knife switches handle 500
watts just fine.

Remember the maximum power transfer theorem? The transmitter probably works
better into some impedances than into others. With an SWR of 1.4:1, the
transmitter will see a resistance between 35.7 ohms and 70 ohms with a reactance
between zero and about plus or minus j15. Knowing the frequency and VF of the
RG-8X, you should be able to estimate the two impedances seen by the transmitter.

I don't have to run a program. Either the program is wrong, you entered
the wrong information, or there is no such thing as a perfect ground.
Just as if I know if I hold a rock in my hand and drop it , I know it will
fall, I know there is no way a 3 foot long antenna will have any gain over a
dipole in an omnidirectional patern. The dipole will not have a gain of
over 9 dbi in an omni patern.

Yes they are. Many have hunted them to eat. There are times of the year that you do not want to eat them as they could have parasites in them. As the temperature turns cold they are fine to eat.

Deer are thought of as varmints the same as rats are to some farmers when they eat their corn fields. Permits can be had to shoot them any time of year (out of the normal hunting season) if they become a nuisance.

Too many of any animal in the wrong area is bad and they must be eliminated by killing or moving.

Yes they are. They are also probably protected during most of the year.
Here in Delaware the season on squirrel is in late September early October
if I recall correctly. Also in Delaware, do not know about other locales,
unless you are a farmer, living on a farm that provides a substantial
portion of your income it would get to be awfully expensive to shoot
squirrels, and get caught at it. There is an exception to most game laws
for farmers in the State - but thinking about it now it might just be an
exception from a license, not seasons.

Well, you sure started something, Stuart.
Alas, it doesn't look like much of it would be
very useful to you.

As for your responders who propose eating
squirrels, one has to accept it, I suppose.
Predation of larger animals on smaller animals
is part of nature's plan, like it or not.

But as for the folks who say they like to kill or
torture animals just for enjoyment, I hope they
are merely trying to be funny--in a bad taste way.

If they are serious, my revised hope is that they get
to meet some of their victims again--accompanied
by much larger friends from the animal kingdom--
at some point in the afterlife.

But this is probably a faint hope, even if there is
an afterlife. Most of the animals would be going
UP, and most sadistic animal-abusers would be
going DOWN. So their paths wouldn't cross.

2848. EZ Way tower sheared hinge pin

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-10 03:12:20 UTC
From: ddl@danlan.*com
Message-ID: <1153864@news1.IPSWITCHS.CMM>
Source record: 110992

After doing some work on my antennas today I tilted up my trusty old EZ Way 40ft tower (circa 1959). To my horror, just as I got within a few degrees of vertical, the hinge pin sheared off on one side. The other side followed soon thereafter. This left the tower sort of hanging from the lip of the hinge and the tilt cable. After I got over the initial shock (and expectation that the tower would fall immediately) I stabilized the situation as best I could with various U-bolt kludges between the ground pole and the lower tower segment. The problem is that I can't see any safe way to bring the tower back down nor do I have the ability to repair the hinge in place (if in fact that is possible). Help? Is this a known failure mode? The tower itself is in good shape and I have kept the ground pole well painted, but I assume that the inside of the hinge just rusted away. It's a little scary having the tower in this state. :(

A dipole has a gain of 3 dbi {DBI} decibels over an isotropic radiator in free space. As to the accuracy of EZNEC take that up with the author, Roy W. Lewallen often posts here regularly, and never with your "knowledgeable?" disdain..

Now back to the antenna at hand:

If you bothered to look at it you would see that it is phased, end fed dipoles. Funny things happen with phased arrays, some of the MAGIC in the MAGIC copper pipe is that phased arrays are generally constructed to obtain at least a little gain. On two the antenna is two 1/2 lambda radiators, on 440 the antenna is two end fed 3/2 lambda radiators.

I have no reason to doubt my ability to use EZNEC, it is by nature EZ and intuitive to use. Mr. Lewallen is owed a great deal for his contribution to the advancement of the radio art.

I would recommend to you that you remember that it is often better to keep one's mouth shut and be thought a fool, than to open it and remove all doubt. And I even gave you two opportunities.

You don't say what VHF frequency, but the Cantenna is probably unsuitable at that frequency. Your amp is spec'd to put out 300W into 50 Ohms, not 35 or 70. It could put out more or less power into a different impedance. Your best bet is to build a little L network right at the Cantenna, adjust it for 1:1 SWR, and then measure the power. Another approach would be to string all the RG58 you own in series with the 8X.

I'll second that. I have an ATAS120 for HF/6m and a dualband 2m 1/4 wave
/ 70cm 5/8 wave for VHF/UHF. I find that combination a good compromise
between performance and "neatness".

Cheers,

Mark.

Less than 150 MHz. Someone else suggested that i place the meter
right at the cantenna, to at least exclude the patch from meter to
dummy load.

Unfortunately, as i have mentioned before, the cantenna is not the
greatest 50 Ohms at anything above 10-20 MHz.

Actually, i read off of my Smith Chart about +/- j20, but you are
close.

Anyhow, my point is that the ham "wife's tale" of adjusting the
coax length for lowest SWR may be truly just a tale.

However, in my case, the SWR doesn't change much, while the
INCIDENT power does!!! To me, this may be due to the fact that the PA
isn't 50 Ohms at the output (I'll bet not many really are), and so a
swing of +/- j20 may improve or degrade how close you are to a
conjugate match.

What do you dudes think?

i would expect that 2" diameter legs would need to be shorter than all wire.
try one of the nec modelers to calculate how much. and yes, you need good
insulation at the feed point and the bottoms of the legs.

Guess I wasn't clear. There are an infinite number of impedances
on a constant SWR circle. The transmitter likes some of those
impedances better than others.

You guys are lucky my XYL isn't watching this thread ... she is
a biologist, licensed by the PA State Game Commission as a
wildlife rehabilitator (she's currently raising ... for release ... about
a dozen orphaned baby squirrels ... probably does about 60 or
more each season, in addition to rehabbing maybe 2 dozen or
more injured adults.)

We have 12 acres of forest here, with squirrels, rabbits, possums,
several dozen wild turkeys, groundhogs, deer, fox, quail, and some
pheasants ... if I shot a single one, she'd shoot me (or worse :-)

Luckily, so far at least, no evidence of the local critter population
developing a taste for coax :-)

I'm not familiar with the tower you're talking about, but in general
if it's not safe to take down without one, consider getting a mobile
crane (maybe a "bucket truck" would have enough capacity,
at that height and weight?) ... better to spend some $
than to risk life and limb (or have it fall on your house and cause
expensive damage).

Way back in the 1970's I visited the National Physical Laboratory (NPL) at Teddington, West London.

I was priviledged to see, but not to touch, the National Standards of the Ohm and of the Volt. There were a number of 4-terminal resistors submerged in a temperature-controlled oil bath. There was about a dozen Western Cells with connecting wires submerged in another temperature-controlled oil bath. There were small fans in the oil to ensure a very slow circulation.

I asked my guide, the physicist responsible for maintaining these vital standards of measurement on which the Commercial, Industrial, Engineering, Scientific life of the Nation is supported, what special sort of oil was used in the baths?

He said it was the same stuff, without the perfume, as young men used for hair oil and came from a tree in Malaya.

>
> Roy Lewallen, W7EL
>

There seems to more explanation needed.

If a lossless dipole is loaded with 100 W of
real power, that is the real power in the far
field, and it is also the real power very close to
the antenna, regardless of the type of antenna.

The value of real power is the same everywhere.

Since real power is in the real part of the
impedance, then how does the value of real
impedance (not the magnitude of impedance) vary
with distance from the antenna?

It seems that very close to (but slightly removed
from) the antenna the real part of the resistive
space impedance is nearly the same as the real
part of the driving point impedance of the
antenna. This real part is then transformed to 377
ohms (real) within the near field, suggesting that
the open space adjacent to the antenna performs an
impedance transformation. The near-field reactive
fields perform this function in some manner.

The real power radiated is found by integrating the Poynting vector slightly outside the surface of the antenna, and is equal to the real power into the (lossless) antenna. This value is constant everywhere beyond the antenna.

Apart from the obvious (and probably unhelpful) comment that you shouldn't
try to tune the ATAS120 while it is frozen, no sorry no thoughts.

Most of my mobile HFing is on 20m where I find that the ATAS120 seems to
have a wide enough bandwidth that I hardly ever need to retune unless
I change band away from 20m. So, it might still be practical if you
don't want to retune while conditions are cold enough that the motor
etc. might be frozen up. I've only been using mine about a month so I
have no idea what will happen in the winter months when it gets iced up.

Cheers,

Mark.

No, you don't want to do that. Put as much loss as you can between the meter and the Cantenna. 100 feet of RG58 will have about 6.5 db of loss. It will make your load a lot closer to 50 Ohms. There are Tables that show SWR as a function of cable loss for a given mismatch. One chart that I have in "Reference Data for Radio Engineers" shows that with a load SWR of 1.4, and 6.5 db of cable loss, the SWR at the driving end is around 1.075. Note that you DO NOT want low loss coax.

Well it would seem that the 'don't use motor oil' comment
which has been passed on by mouth to mouth over the decades
doesn't seem to stand up to scruteny.
Yes, the question is raised so many times over the years
and the same old stories pop up, but without any
substantiation such that it just appears to be gossip.
One statement mentions attack on resisters, where's the proof,
If it is true then it surely can be easily overcome.
Hopefully this time, one of the many posters over the
years on this subject will make observations that are
relevant to the present day instead of waiting for a book.

You can "protect" your coax & control cables with an autoloading 105mm howitzer but for every one of the little beasts you terminate two more take it's place within minutes. Killing and/or trapping them is simply an exercise in futility. I see two choices: Squirrels have strong alergic reactions to cats. Big nasty young female cats preferably from feral stock. And don't feed 'em too much. There's one possibility.

The other is to use coax and control cables which have rodent-repelling jackets and sealants which tree rats don't like. For the coax see

http://www.davisrf.com/ham1/coax.htm#buryflex

There are probably control cables with the same general type jackets. Maybe tree rats don't like silicon sealants, I dunno. Check out

http://www.thewireman.com/products.html

No doubt both Steve at RF Davis and Pres at the Wireman have handled the problem many times, give 'em a buzz, it's only phone calls, save yourself from the goo and ammo expenses.

The figures at:
http://home.comcast.net/~kb7qhc/antennas/Fields/Dipole/index.htm
illustrate just how the dipole's near-field reactance maps out
(without respect for phase, and expressed in SWR relative to free
space Z).

Note that employing the term transform and antenna within the same
context is not de rigueur. ;-)

Hi Reg,

D'you suppose you could explain just a wee bit more what you mean by
"Transmitter Loading Indicator"? I'd have thought my rig's plate
current meter (and its response to the "tuning" and "loading"
controls) handled that pretty well.

Cheers,
Tom

>
> What do you dudes think?

Instrument it properly and answer your own question. Measure the
power at both ends at the same time. Then, assuming you have good
power meters, calibrated to the line you're using, you'll know if the
input end of the coax also experiences the same power difference. If
it does, then it's presumably the output of the transmitter/filter
that changes. You've already offered a very reasonably hypothesis
about why that happens, and could prove/disprove that through some
measurements, too. Is the transmitter a linear time-invariant system?
(Or does it have a load sensor that reduces power output for some
loads?) Can you determine the actual source impedance of your
amplifier, and correlate that with the readings you've gotten?

I trust that the readings you got weren't much of a surprise...

Cheers,
Tom

A TLI indicates whether the transmitter is correctly loaded, or is not correctly loaded, with its designed-for load resistance.

Which is all the operator needs to know and is all the so-called SWR ever indicates.

If you use your plate current meter (minimum dip) to monitor correct loading of your PA, then your variable PA tank circuit becomes the tuner, and you have not merely abandoned the name of the so-called SWR meter - you have completely abolished the instrument from your shack.

Congratulations!

I live on a hill in the country where one can still practice ham radio
without interference from civilization. I used to see quite a few squirrels.
Although a12 gauge shotgun is instantaneously effective, the little buggers
breed like rats, er, squirrels. Since a feral cat I call Max (Short for
Hiram Percy Maxim, since he likes to nap on the S-Line.) has moved in, no
squirrels, skunks, raccoons, snakes, etc. Except for wild dogs, which I
shoot on sight, usually with a Weatherby 7mm08, with Max's approval, I might
add.
I vote for the cat option.

2882. Layout for G5RV twin feedline?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-10 17:22:10 UTC
From: Harry George <hgg9140@seanet.com>
Message-ID: <m3r83tv35p.fsf@wilma.local>
Source record: 110929

I'm putting in a G5RV. The twin lead feedline is of course part of the radiation system. Due to trees, powerlines, etc, I can:

a) Run it horizontally 90 deg away from the dipole, at 5 ft above roof ridgeline.

b) Run it 45 deg down for 15 ft then vertical for remainder (all at 90 deg to dipole). But it ends up between 2 houses, hidden by a hill.

c) Run it at about 15-45 deg to dipole, horizontally even with one leg of dipole.

Of course, one answer is "try them and see which works best". But if this is a well known problem with well-known solutions, I'd like to hear. I'm thinking "a" is my best bet, due to 90 to dipole, but I've never heard of running the feedline horizontally.

I wrote of it before, so I'll be brief and hope I'm not boring. An open-coil hot plate with a ceramic holder to support and contain the nichrome element as filament*. Topped with galvanized window screening, the zinc removed with muriatic acid so as not to noxiously sublime, resting on the ceramic as (literally!) grid. Small glass beads -- around 1/16" -- scattered on it to create a gap and hold the screening flat. Atop that, a pie tin weighted with cooling water to serve as (literally!) plate. With 700 volts on the plate, I got measurable current on my 1000 ohm/volt meter. At -90 volts on the grid, the current was too small to read. The gain was enough to sustain oscillation.

Doug,
Depends on the frequency to a large extent. If
the antenna is for above 10 meters you may see some
slight increase in bandwidth by using the tubing,
same for the 'shortening' of the elements. At HF
frequencies the 2" diameter tubing will have very
little affect on either bandwidth or shortening.
Why would the voltages be higher on tubing rather
than on wire?

I thought that FETs dated to the early 30s. De Forest's "audion" was
invented in 1903 and made long-distance telephony practical by 1913.

Dear Ed:
On my farm, varmints are shot on sight. There is no component of
hunting or enjoyment or torture. It is a matter of stopping theft and
the real danger that their holes present to livestock, humans, and even
farm machinery. (I have a nasty scar on my shin due to a plunge into a
woodchuck hole.) They also pose a danger to drainage systems.
I have never shot at a squirrel. They are very rare here and just
not a problem. Woodchucks and deer are the major problems. Deer cause
hundreds of accidents, some quite serious, per year in this county
alone.
Someone who took delight in torturing anything would be a pariah in
this most rural and tolerant township. That is just not on.

I can't quite visualize what happened, but is there a way to drive the broken pin out, and temporarily replace it with a steel rod? Might require a jack and clamps to line things up. Or, if the thing that holds the pin broke off, can you get a welder out there? You might also want to wrap some cable around the bottom of the tower and the ground pole so the thing can't swing out on you. I assume the ground pole is the raising fixture.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vjdantrlfh50ad@corp.supernews.com>
Source record: 110934

In the fourth paragraph, you say that "real power is in the real part of the impedance", and in the last, that it's "found by integrating the Poynting vector slightly outside the surface of the antenna". The impedance is E/H, the Poynting vector E X H. Clearly these aren't equivalent.

The radiated power is, as you say, the integral of the Poynting vector over a surface. (And the average, or "real", radiated power is the average of this.) The integral doesn't need to be taken slightly outside the surface of the antenna, but can be any closed surface enclosing the antenna. There's no necessity for E/H, or the real part of E/H, to be constant in order to have the integral of E X H be constant.

The driving point impedance of the antenna depends on where you drive it, and it bears no relationship I know of to the wave impedance (which is, I assume, what you mean by "resistive space impedance") close to the antenna. If you find any published, modeled, measured, or calculated support for that contention, I'd be very interested in it.

Roy Lewallen, W7EL

As the squirrel population in my neighborhood went up, they started chewing their way through my attic wall to nest and play. No repellents -- chemical or ultrasound -- worked.

I can not legally use a gun of any kind in this neighborhood. Besides, who has the time to sit around and wait for them?

I finally started to catch them on the ground in Hav-a-Hart traps baited with peanut butter, driving each one around a mile away (across two major roads) and releasing them into the woods. I transported almost 30 of them over a two week period. The populaiton on my property is way down and I rarely see one anymore. I would guesstimate that I get maybe one new one a month from neighboring properties. He quickly joins his friends a mile away. There have been no chew-ins for over six months.

My property is also traversed by rabbits, chipmunks, moles and rats but none of them seem interested in the peanut butter -- which is good because they do no harm.

If it doesn't bother you, you can immerse the traps in a garbage can filled with water (must secure the locking bails first) and save the two mile (R/T) drive.

actually i would expect that a change in E/H would change the driving point impedance and also the performance of the antenna. some possible examples that show this effect are the changes in element sizes when modeling an antenna printed on a dielectric circuit board material or sandwiched in a dielectric media. the change in wire length due to insulation is another example, the dielectric properties of the insulation change the E/H ratio near the wire. some examples may be found in many electromagnetics texts, look at things like dielectric waveguides, or dielectrics in waveguides, wires in dielectric media. even the detailed calculation of fields within a dielectric filled coaxial cable should show this effect, change the dielectric and you change the characteristic impedance... a measurable effect from changing the 'space impedence' between the wires.

2897. Effective area question

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-10 21:57:24 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <bh6f4klin1@news.oregonstate.edu>
Source record: 110940

I'm looking at the form of the equation for the effective area of an antenna and finding it a little non-intuitive...

We have D/Ae=4*pi/lambda^2, where D is the antenna's directivity and Ae is the effective area. Hence, after rearranging, we find that Ae is proportional to lambda^2 or 1/f^2 (f=frequency).

Is this really telling me that if I cut a receiving antenna in the form of a half-wave dipole at 200MHz, it'll only intercept a quarter as much power as a half-wave dipole at 100MHz?

For instance... say the incident field has a power density of 1 W/m^2. A half-wave dipole at resonance is ~73 ohms and its directivity is ~1.64 giving it an effective area of ~.131*lambda^2. At 100MHz, that's 1.18 m^2 and the antenna will produce 1.18 W. At 200MHz, I only get .295W... right? If I attach a ~73 ohm transmission line to these antennas, equating V^2/(2*R) to the powers gives me 13.13V (peak to peak) at 100MHz and 6.56V at 200MHz. This is going to make it twice as hard for me to detect some signal at 200MHz, won't it??? How does the antenna noise scale with frequency -- do I still have the same SNR in both cases?

Thanks for the help,
---Joel Kolstad

We can look at the lowest impedance in particular antenna, which will have higher impedance points elsewhere along its length. Looking at different antennas or arrays we can have antennas with higher lowest impedance. Like folded dipoles and loops. Would that not indicate and provide closer "match" to free space impedance? Again, K8CFU measured that folded monopole "surprisingly" gave higher field strengths than simple monopole radiator. Wouldn't that indicate that there is something "wrong" (good) about higher impedance antennas? Capture area reflected in here?

No, it's really more a matter of how the antenna is oriented relative to
the flow of the Earth's Chi.

Yes. It's half as long, so it won't intercept as much.

Thermal noise has a uniform frequency distribution, so over a given
bandwidth, the noise power is the same at any frequency. You'll have
better S/N ratio with the 100 MHz dipole than the 200 MHz dipole.
Atomospheric noise is usually more important at HF, and it does vary a
great deal with frequency, but at VHF and above, thermal noise generally
dominates.

If you are in the US go to your local Radio Shack. Buy one (sku 420-2385). Should cost less than $5.00, unless you need to attach to 75 ohm connector, then you will have to add the cost of impedance matching transformer, another $3.00 to $5.00.

If do not live in the US, or really, just really have to roll your own the formula is 468/f where f is the frequency in mhz. That comes out to about 4' 9'' long at 98 mhz which is the middle of the band. Solder both ends of the twin lead together, cut one conductor in the center and open it up to about the width of the twin lead. Attach a length of twin lead to this gap.

In either case set the antenna up as an "inverted v", including 90 to 140 degrees between the legs.

Well that certainly seems like something of a raw deal!

I like that way of thinking about it intuitively (it's shorter), although I believe that -- if you match it properly -- if I take that 200MHz half-wave dipole and operate it at 100MHz (effectively becoming a full-wave dipole) it'll actually still collect about the same power as the 100MHz half-wave dipole. (Since its directivity is still about the same... Looking at it the other way, for dipoles < ~0.2*lambda, the effective area is ~.119*lambda^2, and it doesn't really matter if it's 0.1*lambda or 0.05*lambda -- although the later antenna here will be harder to efficienctly match to since it'll have a noticeably smaller radiation resistance).

I suppose those remote controlled aircraft they build that have the arrays of dipoles and diodes on their bellies to intercept microwave radiation to power the motor only use microwaves, then, because they're so much easier to focus than, e.g., a VHF or lower frequency?

> Thermal noise has a uniform frequency distribution, so over a given
> bandwidth, the noise power is the same at any frequency. You'll have

OK, gotcha.

So...in summary... if the cell phone guys had just stuck with AMPS (FM signaling) when they went from 900MHz to 1.8GHz, the SNR of the incoming signal would have dropped by 6dB, correct (assuming the antenna was still the same electrical length)? Bummer...

This should be 'effectively becoming a QUARTER WAVE dipole,' of course.
Sorry. :-) I stand by the rest of the posting.

Of course, you can always increase the size of the antenna to keep the
power density constant!!

That's what all those dishes do...

> large range as the voltage varied during a cycle.

I found such a bulb in the loft of the garage of a house we were renting in the mid-1950s. I had read an article about them somewhere, so I took it inside, screwed it into a lamp near the TV, and, voila, instant Channel 3 TVI (that was the main channel in Milwaukee, WI, then). I put it in a box in my shack, and didn't think about it for some time.

I put up a tower and 20 meter beam. Before the coax was in the house, a neighbor sent his kid over to complain about TVI. I invited him to come over and see that the TV in my shack was not showing any interference, but he declined, and continued to complain over the next few months.

While preparing to leave for two weeks vacation, I had a flash of inspiration. I put the bulb in a lamp, connected a timer to the lamp, and put it in a closet (so the light couldn't be seen in an otherwise dark house). The timer turned the bulb on during evening TV hours.

I left it on for several days after our return. The neighbor never complained of TVI again.

"a" is best. You probably want to keep the feedline from radiating
so install a 1:1 choke at the coax/twinlead junction.

Chop off 3 or 4 feet from both the ends and throw the ends out. Also
check the outer jacket for nicks and cracks. Any nick or crack will
let moisture in and cause problems. Most problems with older cable
will be from moisture seeping into the cable from the ends or through
nicks and cracks in the outer jacket. Do the cutting even if it has
connectors on it because most connectors especially PL-259 type are
not moisture resistant. Also look for places the cable has been
crushed, kinked or flattened. These will be bad spots. I've
successfully used 20 year old cable many times.

dan
Sounds like you got yourself a dandy! Here's my 2 cents for consideration. Do whatever you can to secure the tower in a vertical postion. Tie the tower off so it has to fall where it won't damage other property, or do the least damage, always prepare for the worst. If you can't work safely around it or get safely away if it falls, forget it, get a crane. If the tower has a concrete base get 3 car bumper jacks and some chain for each. Distribute the jacks evenly around the tower base and fasten one chain to each jack and wrap the chain low so the jack can lift. If a jack can get a direct grip on the tower without a chain so much the better. 3 guys might be able to work in unison but maybe one guy one click per jack can do it. I kind of recall that these towers used a steel post for support and if that's the case get some 2 foot pieces of 2" x 12" planks to support the jacks. Think this thru and if it makes sense perhaps you can lift the tower so you can drive the remainder of the hinge pin out. You'll need another hinge pin so get 2, one to use as a driver and one to use as a replacement. This is just a suggestion without any knowledge of specific site conditions but it may give you an idea. In any event make sure whatever you do won't hurt you, your helpers or property. Letting the tower crash safely may be your most economical alternative.
Good luck.

Agreed, and emmersing a waterproof antenna into water will also
affect the input impedance.

> Tam/WB2TT

Perhaps you are correct. That you would only want to use the
meter right at the load if you wanted to measure the real SWR of the
antenna, as the coax loss will improve the return loss (SWR).

I'll try a long piece of RG-58 and see how the incident power is
affected.

No, i understood you alright, and your statement above is
understood and agreed to.

However, in this case, we only have two impedances to chose from
(two different coax lengths).

This is an interesting idea, putting two meters at two different
points. However, they would have to be the same make and model, as
even the digital Daiwa Vs. the analog Daiwa were significantly off.
Additionally, things are further complicated by the fact that the
meters themselves introduce a mismatch, as they are not a perfect 50
Ohm thru.

What do you mean by "calibrated to the line"?

If
> it does, then it's presumably the output of the transmitter/filter

>
> I trust that the readings you got weren't much of a surprise...
>
> Cheers,
> Tom

Not so much a surprise as a disappointment! A difference of 70
watts incident power is totally unacceptable with only 8 feet of coax
length added.

The transmitter does not have a mismatch sensor on it for reducing
power at high SWR. It naturally does output less wattage as the
transconductance is reduced with higher temperatures, but my

measurements were done in close proximity to each other.

Exactly how would you measure the output impedance (S22) of a PA?
Drive it with a small signal (class A, linear mode) in one frequency
(F1), and then inject another frequency (F2) into the output, and then
measure the reflected F2 power? If i remember correctly, that's how
someone was trying to measure S22 at my former place of employment.
But all bets are off as soon as you go non-linear, or non-class A.
S-parameters are supposed to be all small signal.

I don't think you can properly measure the S22 of a class C PA.

Tam brought up the suggestion that i try a really long piece of
RG-58 from meter to dummy load, to make the Cantenna more like 50
Ohms. Gonna try it.

Source record: 110968

I am still trying to decide what type of tower to buy for a house I will be moving into. I would like something I can handle easily by myself, meaning either crankup or tiltover aluminum. I was thinking about maybe a Heights or Universal aluminum 50-60ft on a tiltover base, not the foldover base. To save money I would like to fabricate some sort of steel post along the side of the tower, with a pulley/winch arrangement. Not being an engineer, I am looking for ideas on how high the pole shoule be - maybe as a ratio of the tower height and what would be a good safe diameter pipe. Am I looking for trouble? Typical commercial foldover mechanisms are expensive. Should I just rent a cherry picker for the occasional times I would be tilting the tower over? As light as it would be that should be a solution.

You might live in the woods, but not near livestock. Strays running
stock are always put down. Somehow, those misguided cattle farmers
think beeves are more valuable than somebody's unwanted pet gone
feral. I've known ranchers to pay to have the stray dogs killed.
None, not one, of my dogs has ever run loose for longer than it took
me to catch it. Oh, and you cat lovers out there...it's a PET leash
law, so tie 'em up or reclaim 'em from the pound and pay the fine on
the way in.

Good luck trying to get a response from the Cobbweb folks. I've tried to corresponde with them to ask questions via email several times over the past two years and so far they haven't had the courtesy to reply. Maybe they are just not interested is sales to the US.....or maybe they're no longer in business.

A much better "limited space" antenna is the Hexbeam (www.hexbeam.com). It is more expensive than a Cobbweb but the company is very responsive to inquiries and I've hads several "on air" qsos with satisfied users. I'm saving for one.

> have a noticeably smaller radiation resistance).

That's another real bummer about physics, and one of the major ways it differs from, say, philosophy. Thinking about it a different way just doesn't change it a bit. That's a lesson a lot of the magic-antenna inventors don't seem to pick up on.

> I suppose those remote controlled aircraft they build that have the arrays
> of dipoles and diodes on their bellies to intercept microwave radiation to

That's one good reason. Another is the one you pointed out above -- even though a one foot antenna intercepts as much power at 1 MHz as at 1 GHz, it's impossible to practically extract the power at 1 MHz.

>>Thermal noise has a uniform frequency distribution, so over a given

Well Art, the detergents in modern motor oils are specifically formulated to dissolve carbon deposits and sludge (largely made up of carbon) and keep in in suspension. I'm pretty sure that the resistor in my Cantenna is carbon. Transformer oil is formulated to have a high dieletric strength. Mineral oil is relatively pure, lightweight petrolatum (like liquid Vaseline(r)) and has a pretty high dieletric strength just because of low impurities. Motor oil? I don't know. ATF? I don't know about that either. What I do know is that the designers of my dummy load specify either transformer oil or mineral oil. That's good enough for me. I'll mosey on down to the transformer shop of the local electric utility and buy the folks there a round of coffee in the morning or over to the veterinary supply and buy a gallon of mineral oil U. S. P. I think it's safer that way. We hams are in interestingly cheap lot. We'll spend thousands on a new rig that could break down tomorrow and then pour a gallon of "whatever" into the dummy load instead of spending twenty bucks for mineral oil or fifty bucks for MFJs transformer oil. This in a unit that with ordinary care will last a lifetime. Sheesh!

Go back a bit to the 'Old Coax' thread. Someone recommended cutting three
or so feet off each end of the old stuff. See if you can get those 'end'
cuts, and use them as bait in squirrel traps!

> length added.

But the load presented to the amplifier is totally different in the
two cases, most likely. Only if the amplifier's output impedance were
the complex conjugate of the line's, and the line were lossless, and
the amplifier behaved as a linear time-invariant system would you
(should you) expect the power to remain unchanged.

> Tam brought up the suggestion that i try a really long piece of
> RG-58 from meter to dummy load, to make the Cantenna more like 50
> Ohms. Gonna try it.

Or just tune the load to zero reflected power after you're sure the
meter is properly calibrated...but that can be a catch-22 situation
that the really long RG-58 can help with. Be aware, though, that
"50-ohm" line seldom is -- it can be off 5 ohms or more. It's a cause

of some consternation to those of us involved in calibration of precision RF test equipment.

Load-pull techniques are commonly used to characterize RF source impedances. You make known incremental changes to the load, and deduce from the change in output power what the source impedance is, assuming it's a linear time-invariant system. Note that adding length to a mismatched line is one way to make an incremental change to the load... I wouldn't necessarily say that the output impedance of a class C amplifier is meaningless, but it may well not be constant for all loads. and may depend on parameters you'd have trouble controlling from day to day.

Cheers,
Tom

This means your shield has RF on it .
Also triming cable has nothing to do with SWR. Trimming the cable will change the impedance the transmitter sees if the transmission line has standing waves on it.

I hope this is a wifes tale that has long been discredited. Trimming cable
changes the impedance seen by the transmitter with no change to SWR. It is
true that there are a lot of people who dont understand the difference.

That would give you 13db of return loss which would be an SWR less than 2:1
even if the far end was a dead short.
Given his current SWR I woud say this would result in a return loss of
around 30db. Numbers are a lot of by guess and by golly but think I am not
too far off.

Its not gossip or old wives tale, I know first hand that motor oil will break down the varnish used on a lot of electronic parts. I had some old carbon resistors that fell in a bucket with some used motor oil. Set there for at least a couple of years in my storage shed. All the markings were disolved. It is my understanding that carbon compostion resistors have the varnish on them to keep contaminats from being absorbed by the resistors so it is reasonable to assume that removing it is a bad thing.

2939. Re: Effective area question

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-11 10:10:07 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <bh7q1v$9nq$1@sparta.btinternet.com>
Source record: 110882

It's easier to begin with the apperture of an isotrope which is the surface area of a sphere of radius Lambda/(2*Pi) = 0.1592 wavelengths.

Note, it is independent of the physical size of an antenna - only on wavelength or frequency.

So apperture of isotrope = Square(Lambda) / (4*Pi) square metres.

The gain of an isotrope by definition is unity.

It is of interest that at a distance of 0.1592 wavelengths from an antenna the radiated field is of the same order of magnitude as the near field.

You mean the directionality of the couplers inside the meter? I
don't know.
You can adjust the needle on the analog Daiwas to read zero watts with
nothing hooked up to them.

I'm not sure i agree with your statement as you have written it.

The power would remain the same only if the load and the line
were perfect 50 Ohms and also lossless, then the length of the coax
should not matter at all.

This is certainly not the case on our bench, which is a problem,
because i want to have an approximation of how it will perform
attached to the antenna before i ship it out to the customer. A
difference of 70 watts is not acceptable.

Oh, definitely, especially the cheap stuff. But if the RG-58 went
around the world a couple of times, the end could be open or shorted,
and you would still measure 50 Ohms, most likely.

>
> Cheers,
> Tom

Right, they did plenty of load-pulling on FETS at my former place
of employment. I think they may have been more meaningful for class A
linear CDMA PAs. But finding the max power transfer impedances with
small signal class A measurements doesn't guarantee that these will be
the optimum impedances the transistor wishes to see in class C mode.

But i don't think there is a practical way to measure the S22 of a
high powered Class C amp. Most companies don't really seem to care
how close or far from 50 Ohms it really is, all they care about is the
%PAE and Pout and harmonics dBc going INTO a 50 Ohm system. But even
ensuring that your bench will match your customer's bench is a
difficult thing.

Russ,
The point I am making is that some comments are repeated
so many times they take a life of their own
Think about it, the resistors of old are a far cry from
the carbon resistors of today which are not as porous,
if it is a worry then coat it with epoxy !
Then there is the "rust" question, the paint cans of today
have a teflon liner ! Even the latest ham data states that
motor oil CAN be used (no, it will not explode !) but raise
a question of "life", possibly a suggestive comment that you
change the oil every 5000 qso's.
Certainly industry gives a good guide as to what is the best
to use for their circumstances but it doesn't rule out every
thing else for all time, and this includes motor oil of which
there are many types.
Regards
Art

DX QSOs with your dummy load count as "harsh conditions", so you've got to change the oil every 2500 DX QSOs if you don't want your dummy load wearing out early.

:-) The meter-needle zero generally not a very big part of the
problem! Yes, it's the coupler (bridge) inside that you want to make
sure is calibrated for your reference impedance. If it's not
adjustable, at least learn what it is calibrated to, or how good it is
for your reference impedance.

So you've come back around to what some of us here have been saying
for years. A transmitter or amplifier may be designed to work
optimally into some particular impedance (say 50 ohms), but have a
source impedance vastly different from that. Whether it's a
measurable impedance or not is moot: what matters is that you present
a reasonable load to it. There ARE cases where a matched source
impedance is important, but they are rare in ham transmitter work.

The easy way to insure proper operation is to present the
transmitter/amplifier with the right load. A properly calibrated SWR
meter (or as Reg would have it, a "transmitter loading indicator")
will tell you when you have such a load. Yours is telling you that
you do not. In such a case, I'd work on a match to the antenna (or
the Cantenna or whatever) first--well, right after making sure the
meter was telling me the truth or something close to it. When you get
that correct load, then the length of coax won't matter noticably,
assuming the SWR meter is calibrated to the line impedance.

You generally don't have control of your customer's bench, but you can
specify some particular load impedance and then make sure you test
with that, and leave it to the customer to insure that they provide
that load. It's reasonable (if not common) to specify a range of load
impedances over which some perhaps slightly reduced performance is

achieved. You may, for example, get more power but also higher distortion products, at a non-optimal load.

Cheers,
Tom

Hi Tom,

This is kind of a chicken and egg problem.

Calibrate the meter against the load.

Calibrate the load against the meter.

It would seem that discussion would eventually get around to bringing in a known and stable reference. The length of lossy line would suffice for a rough cut solution but still leaves a bench full of rather sloppy instruments.

I was thinking (finally) about simple dipoles and such and have this question:

I plan on constructing some simple dipoles. For fun, I have been modeling them using EZNEC. It seems the "common" practice is to feed the antenna with 50 ohm cable. The antenna feed point impedance is usually ~70 Ohms. Would it make more sense to feed a dipole with 75 ohm TV coax to keep the SWR low on the cable and have the mismatch at the radio? If I plan on using an antenna tuner, would this setup be preferred over 50 ohm feed cable? Does it really make any difference?

Just Wondering,

Tom

I imagine that all of the (unradiated) CQs being fed into the dummy
load end up being absorbed by the oil and eventually precipitate out
as a sludge on the bottom of the can?

Maybe there's a way to filter them out of the oil and recycle them.

However, a 50 ohm SWR meter reading will change as one changes the
length of the ladder-line. When the 50 ohm SWR meter reads 1:1,
the transmitter is seeing 50 ohms. That's how I tune my dipole.

==========

Tom you are quite correct. The lowest loss on a transmission line occurs when the line impedance is matched to the antenna feedpoint impedance. So a standard 75-ohm line is a better match to the centre of a simple 1/2-wave dipole which is around 70 ohms when at exact resonance.

Furthermore, the attenuation of a 75-ohm TV line with the same overall diameter is less than a 50-ohm line. Especially if the 75-ohm line does not have solid polyethylene insulation but is partially air spaced. The two effects, between them, may result in a noticeable increase in signal strength on the 10m band if the feedline is very long, say 150 feet or more. For short feeders there will no practical difference between the two impedances.

But coax of any impedance limits use of an antenna to frequencies at which it is 1/2-wave resonant and 3/2-waves resonant.

To take advantage of a tuner you must use a balanced high impedance feedler such as 450-ohm ladder line or 600-ohm open-wire line. For the same weight of line the higher the impedance the better. Line loss can then be reduced to a negligible amout. Less than either 50 or 75-ohm coax at any frequency.

But the big advantage of the high impedance line is that its very low loss applies to ALL HF bands from 160m to 10m. The antenna does not have to be resonant at any frequency. It can be of random length and work all bands if it is long enough at the lower frequencies. The high-Zo feedline can also be of random length. Best to bring it all the way from antenna into the shack near the tuner.

You will never have a better, all-round, all band antenna than a high dipole fed via 600-ohm line, overall dipole length as long as you can fit into your back yard.

So Reg, would you advise using a (4 to 1) balun with the open wire on one side, and a short run of coax, say 20 feet or so on the other to the antenna tuner? Would this work well? Does one need to 'make' the open wire feeder, or is the commercial stuff you buy ala ham coax suppliers good enough?

regards, Jerry

2955. Electronically tuned Helix

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-11 20:07:12 UTC
From: whru@msn.com
Message-ID: <e52bdeaf.0308111207.48984cf4@posting.google.com>
Source record: 110898

A few years back I read a paper which described an electronically tuned HF Helical antenna. It was a shunt fed Helical monopole which employed electronically switched PIN diodes to add or subtract helix turns. As far as I remember a 6ft helix antenna was resonant between 4 to 30 MHZ by switching the PIN diodes. Diameter = 19", 20 turns, Q<50, average power = 400W.
Now the question to the antenna experts: was such an antenna ever developed and manufactured. If yes, who did.

Raising a tower whether fold over, or using a raising fixture is a
whole series of tradeoffs.

Some things to think about:

A lot depends on how much room you have...can you lay a 50 foot tower
straight out?

Actually with a tilt over base three men can walk up a 50 foot ROHN 25
G, but not with much of an antenna on it. At 40 foot three men can
walk up the tower with a small tribander on it.

If you want 50 feet and plan on using a raising fixture (post int he
ground) as opposed to a fold over, it can take a pretty hefty post
with a heavy base.

Remember that with a raising fixture the loads exerted on the base
hing(s) can be tremendous. Make sure th tower is capable of
supporting that much diagonal pull. When you start raising almost all
the pull is at 90 degrees to the base. Something the tower legs may
not be strong enough to support.

The taller the fixture the less load on the tower legs. The farther
out the attachment to the tower the greater the load on the tower legs
and up to a point the less effort required to raise the tower.

When pulling a tower up using a raising fixture the two points with
the largest forces are the base and the attach point. Raising the
tower so it's already part way up...supported by a ladder, or some
such device can reduce the side load at the attach point and base
substantially. Depending on the size/weight of the antenna, mast, and
rotor the weight supported at the attach point can be considerable.

>
The taller the raising fixture and the farther out the attach point
(in general to a point) the less side load at the attach point.
OTOH the taller the raising fixture the heavier the material required
for the fixture.

One additional point. IF you use a raising fixture AND have several
men helping by lifting and pushing against the tower it can greasily
reduce the effort required by whoever operates the raising fixture and
it can reduce the side loads on the tower at both the attach point and
the base.

Typically fold over towers are reinforced at and within some distance
of the pivot point.

Mine, we installed one section at a time using a gin pole.

>
> The power would remain the same only if the load and the line
> were perfect 50 Ohms and also lossless, then the length of the coax
> should not matter at all.

It's true that if the load and line are the same impedance (e.g. 50 ohms), no matter what the line length is, you'll present that impedance (e.g. 50 ohms) to the source and it will deliver constant power, independent of line length. If the line is lossless, then the power delivered to the load will be independent of line length. Fine. But your OP suggested that the load is NOT the same as the line impedance (indicated SWR not 1:1), so another case is perhaps equally or even more interesting.

If you require that the source impedance match the line impedance (and because the line is lossless, it's impedance must be purely resistive), then the net power delivered to the line for a given SWR on the line is invariant with changes in line length (changes in reflection coefficient angle in the load presented at the source). (Straightforward though perhaps tedious to prove, or just convince yourself with some examples.) Since the line is lossless, the power to the load is invariant. That's the scenario I suggested above.

So with a lossless line, and EITHER the load OR the source matched to the line impedance, the power delivered to the load will be invariant with line length.

As you also noted, however, transmitters/power amplifiers are seldom going to be 50 ohm sources (though designed to work into 50 ohm loads), and therefore you should expect the power to vary with the load--in other words, with the angle of the reflection coefficient in a 50-ohm-reference system.

Cheers,
Tom

Here they even have limited hunts in park areas and the city forrest
to reduce the over populations. Every time they do it's a battle with
the environmentalists. I guess they figure starving to death, or the
deer being killed by dogs or coyotes is more humane.

At least for the time being herd management and common sense is
prevailing.

I've not had any problems with squirrels getting into the coax...yet.
Maybe it's my cat chasing them (and the stray dogs) out of the yard.
Big cat. Hates dogs. Loves kids. Chased every dog in the
neighborhood home except one. They ever meet and I'll probably be
looking for a new cat, although he did get into a fight (attacked) a
full grown black lab that came in to the yard...and won.

The dog walked up behind the little neighbor girl and the cat went
ballistic.

When he was much younger he took in after a squirrel. The squirrel
went up a tree with the car right behind it. The squirrel bailed from
something like 25-30 feet up. The cat never slowed and went right
after him. However when the squirrel went up the next tree the cat
stopped at the bottom and just looked up.... I think he learned
something that day. <:-)) driveways are pretty hard when hit from 30
feet up.

That's one of those "it all depends".

Here in Michigan the farmer does not need to purchase a small game
license to hunt on his own land. For deer, he does.

If in the specific case of critters destroying crops as in major
damage they can apply for permits to hunt them. Those permits are
usually issued after a visit from the DNR (in some cases)

Unfortunately coax doesn't count, but some department of Natural
Resources (or what ever they are called in your neck of the woods)
will help you live trap them for relocation.

(following up to my own message)

Based on the responses I've received it seems that my hinge is different from everybody else's. The ends of the tube are welded shut (and possibly the pin is welded to the end or ends--I can't tell). There are no grease fittings. So while I could probably jack the tower up such that the hinge is correctly aligned, I can't simply drive out the old pin and put in a new one. I think the end welds have to be ground off and then maybe repaired after the new pin is in place. Hopefully a welder/machinist will be able (and willing under the circumstances) to do this. It might be nice to have a couple of lugs welded near the top of the pole as well. Then I could run a safety chain around the tower to prevent it from falling off the pole if something like this happens again. In fact, it might be a good idea to do this first, making the subsequent work safer.

In theory, yes. It would be on the constant VSWR circles, assuming
50 Ohm transmission line!

Trimming the cable WILL have something to do with the series
reactance that the PA will see, and may affect the impedance match.

You want a thrill...I was landing my airplane (a 3100#, High
performance/complex/retractable at the Gladwin Airport (GDW) one night
when a big doe decided she wanted to be on the other side of the
runway

http://www.rogerhalstead.com/833pics.htm (bout 243K)

The mains had just touched down the nose gear was still up when she
charged across. Her head hit the underside of the leading edge of the
right wing about 2 feet out from the fuselage. Just about inside the
prop circle.

The impact drove her head down and then the right main hit her with
the wheel running over. It tore the gear doors right off and busted
the stainless steel brake line.

All this at something like 70 MPH drove the right wing up and of
course the left wing down. The wing tip was probably within 3 or 4
inches of hitting the runway. I could see the runway lights above it
as I was watching out of the corner of my eye.
I managed to maintain control, riding down the runway on the left
main only. I didn't even know if I had a right main still attached.
I kept it on one wheel as long as possible and then the right main
settled onto the pavement. (Yippie! I had one!)

Now I was riding on both mains with the nose gear still up in the
air...I didn't know if I had one of those either. Fortunately I did
and the roll out was uneventful...other than I discovered that broken
brake line which resulted in only having brakes on the left side.

Between the brake line, tire, gear doors, hinges and a very small dent
on the underside of the leading edge the freight came to a bit over
$5,600. Those little tiny stamped hinges for the gear doors are $480
each.

They said it was either the third or fourth deer airplane accident in
the previous two weeks.

I've never seen an SWR meter that wasn't designed for 50 Ohms...
:/

If you mean adjusting the meter so that the forward power is full
scale deflection, well, that's not needed for a cross-needle SWR
meter.

I'm gonna try the long RG-58 trick...

I've never seen an SWR meter for other than a 50 Ohm system, so
i'm not quite sure what Tom means by all this. I certainly can't
easily adjust the directionality of the couplers inside my Daiwa!

It would be nice to have a reference 50 Ohm dummy load, especially
a higher power one, that stayed close to 50 ohms even at higher
frequencies. In the meantime, i'm gonna try the long RG-58 trick.

If you want 600 ohm I think you will have to roll your own. I use
commercial 450 ohm line myself. There will be a balun in your tuner (if it
will directly feed ladder line) so why not just run the wire to the tuner,
and not bother with coax at all.

Many want to use a few feet of coax in tandem with parallel wire [open wire 600 Ohm or 450 Ohm window line] just to pass the transmission line "through the wall".

If passing the line through the wall is the problem then just use a foot or so of electrical mains "zip cord" for that short passage. Simply solder a short piece of zip cord into the 450 Ohm window line at the appropriate place to allow the line to pass through a small 1/4 - 1/2 inch hole in the wall. The "impedance bump" caused by the short hunk of zip cord will never be noticed throughout the MF/HF bands.

Tom,
If you hadn't said 75 ohm TV coax, I'd say it would
work just fine either way. If you would change that
"TV coax" to something like RG-59 (or whatever the other
size of 75 ohm cable is) you would have much less trouble
making connections. The TV stuff uses aluminum braid, which
is a real P.I.T.A. ...

My 2 cents (wont even buy a lolipop any more!) From the old VHF,er magazine, couple of thoughts: 1) Very lossey coax will show a prefect termination impedence even if open, or shorted, if sufficiant length is used (for the coax's attenuation) . For that reason, still keep a coil of RG-8 size coax (for power dissipation), with RUBBER DIALECTRIC (was origianlly made for attenuators at the Microwave Region) Even at 80 meters, with no load , has very low SWR! At 10 meters, and up, with a UHF connector on one end, and a N connector, on the other, with NO TERMINATION, makes a great dummy load to 2-300 watts!. and, 2) Just because you think you have a great match, can be a random event. to test , place a 1/4 wavelength piece of coax (figuring with velocity factor). If the SWR stays flat, you can assume a good match, if, howerer, the SWR climbs, then you need to check for a proper match (this will throw the worst condition into your coax , with this extra length, kinda like the opposite of trimming coax for the best match legends of old CB lore)! as info, Jim NN7K

Yes, the impedance "bump" isn't a problem, but I would be concerned
about voltage breakdown. Most zip-cord is rated at a maximum of 600
VAC and it is quite possible to have voltages higher than that on a
transmission line.

Where can I find an inexpensive, freestanding (or lightly guyed), antenna tower? It doesn't have to support a lot of weight - a couple of small 2m radio antennas and one or two scanner antennas. And it also doesn't have to be very tall - thirty to forty feet would be just fine. I'm sure others would be interested in this also.

Heh! As one of the veterns of the squirrel versus human wars, I tried the live trap route, and it doesn't work at all. You might catch one, but that's about it. Here in the squirrel capital of central PA, we have dozens of the little buggers. I had to seal up every opening in my house, and seal the corner molding on my vinyl siding. Brats would climb up there and munch a hole into the attic. Then they got in through the triple walled chimney. I found that by chance. So I had to put wire cloth on that. But wattya do about the ones who already got into the attic? I made an escape route by drilling a hole in the side of the house entering into the attic, and put a long narrow box over it so that would jump out when they got thirsty and hungry enough. We're at a standoff for the moment......

Thanks for the feedback - I am looking for advice on a safe method
to do this, if I should. I figure an aluminum tower will be easier to
raise, but of course at the same time aluminum will be weaker than steel.
The foldover system that Heights towers has is somewhat amazing to me. It
seems to me that there would be a huge amount of stress on the system.

This could be a whole 'nuther thread. For a reference, I don't have
any difficulty making a 50 ohm load with 40dB return loss out to a GHz
or so for less than $10, and most of that is the connector. Does
someone need to document how to do that? But I submit that if you
want accurate SWR measurements on a particular line, you should
calibrate your SWR meter to that line, and that doesn't take any
reference except the line itself.

Cheers,
Tom

Not claiming they don't exist, but I have never seen a raising fixture for other than a crankup tower. Bite the bullet and buy the stuff that is all supposed to work together. If you extrapolate from how they are set up, a raising fixture for a 60 foot non crankup tower would be about 30 feet high.

==========

To add a length of coax, balun or not, to the end of a long, beautiful, exceedingly low-loss, open-wire transmission line should be regarded as a criminal act worse than horse-stealing and be made a hanging matter.

The correct, most efficient arrangement is to connect the line direct to the tuner via a 1-to-1 current (choke) balun. The length of coax between tuner and transmitter can then be as long as is necessary to reach.

A great length of coax, a horrid lump of capacitance, on the antenna side of the tuner will also restrict its impedance matching range and possibly increase tuner losses.

A 1-to-1 choke balun is just a few (8 or 10) turns of twin speaker cable (18 or 20 gauge) wound on a ferrite ring, or more turns on a ferrite rod with a length of the same order as the ring's diameter.

The actual impedance of an open-wire line is of no consequence. It so happens when the wires are spaced apart 100 times wire diameter Zo is about 600 ohms. 18-gauge wires spaced 4 inches = 600 ohms.

14-gauge wire spaced 2 inches makes a nice line. At 30 MHz, loss = 0.15 dB per 100 feet. With SWR = 6, loss = 0.48 dB. When used as a 1/4-wave matching transformer, Q = 550.

The problem is flexing in the wind and metal fatigue. But amateurs don't need a feedline to last a lifetime - projects don't last that long. Very tedious to homebrew so most people seem to settle for 450-ohm ladder-line. Choose the heavier wire gauges. Don't bother with flimsy 300-ohm ribbon stuff.

Problems involved with extending lines into the shack, like Mark Twain's death, are much exaggerated. Insulate the wires and bring them close together through a single hole in a window frame or even a wall. A little extra capacitance due to close spacing over a length of a few inches is electrically entirely un-noticeable. You've only to look at it to realise that. Ignore gobble-de-gook about impedance bumps on lines intended to operate with high efficiency at high SWR.

If you like amusing yourself with numbers, to analyse performance of any HF dipole with any arrangement of twin-line + coax line + balun + tuner, download program DIPOLE3 from website below.

If they still make it, the Rohn HBX series would be the least expensive.
(Notice, I didn't say cheap). It comes in 8 foot sections that bolt
together. The top section is the skinniest, about 6 in on a side, and
sections get progressivly larger towards the bottom. It is light enough that
one person could lift a 32 foot tower. Good for 10 sq. ft. of antenna. Self
supporting, if you mount it on a concrete base.

Another low end tower is the USTower MA40. This is a tubular crank up tower
with a hinged bottom. You either need their raising fixture (expensive) and
a concrete base, or support it at about 8 feet against a building. It comes
with the building support bracket; this method only requires a few bags of
concrete. Also rated at 10 sq. ft. of antenna.. With this tower the rotor
can not be mounted inside the tower, and you can not use a thrust bearing.

If you live in a fringe TV area that recently got cable, you should be able
to get a TV tower for free if you take it down. The ones I see in South
Jersey seem to be 40 - 50 feet.

It is a rather simple matter to perform and I am sure the Daiwa has adjustments (few instruments are calibrate for life at the factory). These are usually variable resistors (trimmers) for forward and reverse for each power setting. There are usually capacitors (trimmers) that adjust for directionality over frequency. They affect power readings, but should be left to the juggling of the inevitable errors (the art of accepting the least error from all sources). If the Daiwa lacks these, and you are serious about using it; then this requires you to make substitutions with existing components such that you force some variability into the game where there was previously none. This is not trivial, but neither does it require a PHD. One need only be mindful to dimensions as they relate to wavelength and issues of stray coupling (proximity) which, of course, means lead length; component composition, and package bulk.

You simply approach the problem as calibrating TWO power meters into a known load (the 50 Ohms, regardless of how that is accomplished). All it takes to do the reverse power is to simply invert the connections. This also confirms the balance. Driving into a known load will always evidence a zero return power regardless of direction of connectors. This is not always borne out in nature or over the various power ranges, and frequently calibration is the art of accepting the least error across all used settings. Calibration is often performed through many iterations as the trimmers sometimes present interaction. If you expect to work in one power range at one frequency, you can optimize your errors.

As for the calibration of absolute power (rather than what would be described above as relative power). That is the provence of the Metrologist and the well heeled amateur. Appeals to having been confirmed against a Bird Wattmeter is common (and a rather comfortable illusion). It will suffice if you can tolerate 10-15% error (barring

a recent trip to the Metrologist's bench with the return of the necessary certificate and actual measurements). "Any" Bird is no more accurate than 20% with hope and wishes - especially when bench practices include poor loading and poor source Z control.

Is that something like a Weston Cell?

On a serious note, don't overlook refrigeration oils, they are high quality, light, dry oils for immersed motor windings, and available in smaller sealed tins (around 5 litres).

This is very interesting, as it may indicate that the "wife's
tale" may have some validity in _some_ cases.

For example, if your antenna happens to have an impedance of say,
60 Ohms, and your transmission line happens to NOT be a perfect 50
Ohms (usually the case), and happens to be around 54.8 Ohms or so...
then at odd integer multiples of 1/4 wavelength (velocity factor
included, of course), you will be right on 50 Ohms.

Additionally, as we have mentioned before, PAs rarely have 50 Ohm
output impedances anyways (who actually measures this??). So an
impedance transform via perfect 50 ohm coax length may indeed get you
closer to a conjugate match and higher incident power, which may
improve your VSWR (which is based upon the incident and reflected, of
course).

You're right about this, and it reminds us that if there is any
loss at all, we theoritically move away from a purely resistive
characteristic impedance into a complex one. This furthers the
complexity on the problem, as we must expect reactance in our coax.

We'll have to wait for the room temperature super-conductor that
is also flexible to come closer to the ideal 50 Ohm test setup!

> So with a lossless line, and EITHER the load OR the source matched to

Agreed, as the impedance will not move on the Smith chart.

But can you make a 50 Ohm dummy load with those specs that can
handle
300 Watts? The stays at 50 Ohms out to at least 200 Megs or so?

And i'm still not sure what you mean by "calibrate your SWR meter
to the line". All the SWR meters i have seen are all for 50 Ohms.

Could you tell us the exact procedure?

Almost correct.

The transmitter output impedance has no effect whatsoever on the line's SWR.

I have a 25 ft pole made of plasticised paper, in 4 sections, with brass inserts at each end. Ex-army. I paid 5 GBP (nearly a week's pay) for it in 1953!

I used it guyed with light plastic line. It supported a 10 ele 2m beam for several years.

2994. Eznec modeling loading coils?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-12 11:23:27 UTC
From: k3bu@aol.comnoSaddam

Source record: 110837

Question to Roy,
can EZNEC model loading coils in loaded antennas, like mobile whips including the physical properties of the coil?
I just had some exchange with W8JI on eHam.net
http://www.eham.net/articles/5998
where he is ignoring the fact that loading coil is part of the radiator and its physical properties, where length to diameter ratio have impact on the current distribution in the coil.
He is claiming that modeling programs confirm his statement that the current is the same at the both ends of the loading coil (close in short coils) . I am having hard time to see how the modeling program is capturing physical properties of the coil besides inductance, Q etc.
W9UCW has done considerable amount of work on the subject and has measured that the current diminishes in the loading coil away from the feedpoint.

Thanks!

50 +/- what? What return loss are you shooting for in this 300W dummy load? Do you really need 40dB, or is 30dB good enough? I believe it's possible to bootstrap yourself into measurements that are far more accurate than you'll need for what you are doing, and do it quite economically if you don't count your time. But you ought to first ask yourself just what accuracy you really need, and understand why.

Probably one can make a quite reasonable broadband power load, at least to your 200MHz limit. There have been some good construction articles on making tapered shields for power load resistors, for example, to get good high frequency performance. But if you can make just a good low-power one, you can bootstrap your way to accurate measurements at high power. Use the low power one to insure your directional coupler is good to some tolerance, and use that to tune your load at whatever frequency you wish to check. Even your cantenna should be low enough Q when tuned with an L network that it would be acceptable over the whole of the 2-meter ham band. It's tedious, but you can re-tune for any spot frequency inside or outside the ham band. And given one accurate load, you can determine what impedance your long, lossy coax is and then use that as a dummy load (probably quite broadband). For example, if your cantenna is good enough through 30MHz, and pretty good at 54MHz, and under 2:1 SWR at 150MHz, then perhaps enough RG-58 to give you 10dB loss at 150MHz (150 feet or so),

feeding that cantenna, would work fine from 1MHz to 1GHz. Just beware of power dissipation in the line itself at higher frequencies. You can even cascade large coax, small coax and the cantenna, to insure power handling.

Beware of harmonics messing up your readings!

Also, you'd probably do well to consider how small a change in power results from a modest load change, for various source impedances. What's the worst case? What's the best? Is there a reason it might be nice if an amplifier output was "reasonably close" to 50 ohms, or doesn't it matter at all? If you think all this through, you may realize that if your dummy load is even only 20dB return loss, it will be just fine for the measurements you need to make. But YOU should convince YOURSELF of that, or of what you really do need.

> And i'm still not sure what you mean by "calibrate your SWR meter
> to the line". All the SWR meters i have seen are all for 50 Ohms.
>
> Could you tell us the exact procedure?

Of course not; I know nothing about YOUR SWR meter. If you understand how yours works, you should be able to see how to adjust it, though it may not be worthwhile. To a close approximation, practically all of them work by sampling the line current and voltage at a point. The current is somehow turned into a voltage, and if you adjust either the voltage sampling percentage or the voltage produced by a given current, you will have adjusted the calibration impedance. At the high frequency end, you may need to worry about reactive or phase-shift effects. If it's not adjustable, don't you at least want to know WHAT impedance it's calibrated for? Or at VERY least, what it reads with a 50 ohm load?

Cheers,
Tom

Engineering a tower installation is not rocket science but only for
for those educated and experienced in the field of structural analyses
and design. Towers "engineered" by those who don't have appropriate
backgrounds are potential deathtraps.

Don't raise a full-height tower via a pole, cherry picker or sign
crane unless you have a grip on all the reaction forces & streses on
the structure based on the location of the lift point.

Select a catalog tower and stick 100% to the manufaucturer's
installation and operation directions. It'll cost more but you'll
sleep better.

3001. Re: Eznec modeling loading coils?

Newsgroup: rec.radio.amateur.antenna
Date: 2003-08-12 16:57:17 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vji739lhs34607@corp.supernews.com>
Source record: 110844

It's not practical, and often not possible (due to inability to model proximity effect), to model a loading coil on a turn-by-turn basis. Where a loading coil is physically long enough to have a current gradient across it, I've always believed it's adequate to model it as a wire whose outer diameter is the same as the outer diameter of the coil. Usually, a single lumped inductive/resistive "load" placed in the center of that wire is adequate, although if the coil is particularly long, you might want to split the load into several equal pieces distributed along the fat wire.

This approach assumes that the current gradient across a coil is the same as for a wire of the same outside diameter as the coil. I don't, however, have any measured data to confirm this. It would be a fairly simple matter to put toroidal current transformers just above and below a coil and compare their values to what EZNEC or other programs report. If anyone has done this or is interested in doing it, I'd love to see the result along with a detailed description of the methodology.

Hi Roy,

Entirely incorrect.

Transmitter output impedance that does not conform to transmission
line Z, when presented with a mismatched load through that line, adds
mismatch uncertainty in the form of an indeterminate SWR and
indeterminate Power to the load.

This has already been demonstrated twice. This has long been
documented with NBS/NIST references going back 4 decades. There is
nothing mysterious about it at all, and it conforms to the rather
simple principles of wave interference so poorly presented by Cecil in
months past.

Hi Yuri,

When I open the load dialog window, it presents R in some form or
another (the answer to your Q provision). Are you concerned the
program will treat the load as an infinitesimally small object? If it
does, you could decimate the coil inductance and distribute it across
10 segments whose span is equivalent to your anticipated physical
length. Perhaps a lot of trouble (and perhaps there's another, better
way), but it seems to be the price of your query.

Hi Fred,

Seems unlikely. PIN diodes (or any diode for that matter) would have
a very difficult time switching 300W voltage potentials far in excess
of the diode's own intrinsic boundary potential. PIN diode switching
is most often employed in receive circuits where the signal level is
considerably smaller than the switching potential. Then, on the other
hand, they may have huge power sources capable of blocking the RF
potential swing anticipated at the node the PIN diode serves (talk
about cost!).

He sed:

"The transmitter output impedance has no effect whatsoever on the line's SWR."

THIS IS ABSOLUTELY CORRECT!

3006. Horizontal J type (G2BCX Slim Jim for those who remember)

Newsgroup: rec.radio.amateur.antenna

Source record: 110849

Back in the early 80's when I gained my class B, I built myself a 2 metre slim jim out of 3 mm wire, shoved it inside a piece of pvc wastepipe, and it worked a treat. I could hang it almost anywhere with a loop or a hook, lean it against a wall or a tree. I even used it on a bicycle with an FT290R as a /M once - but I was much younger then

Later, I built an 11 metre version from 8mm copper microbore for a friend. It worked very well with an swr of 1.5 or less on the mid band and no greater than 2.6 or so at the extremes of the 5 'bands'.

I've been thinking (always a silly thing for me to do) and I've pencilled a design for a 20 metres wire version on my computer desk and it seems to have everything I need - specifically the feed point can be very close to the shack, it doesn't need buried counterpoises or an rf earth and I can rig it "hammock style" with cord through a couple of cheap eyebolts and pulleys without climbing. My math needs refining, and I've no idea what the bandwidth would be, but it shouldn't be difficult to make one from 1.5 or 3mm copper wire or braid, or perhaps 4mm aluminum wire and 1" pvc waterpipe spacers and fire it up.

Or perhaps not. There could be good reasons why I've never heard of a 20m Slim Jim, and if it was any good, why isn't everybody using one? If I've invented something new, it's mine I tell you.... Oooh, I feel better now

Has anybody tried using a Slim Jim horizontally on HF other than on 10M?

I used steel wool and WD-40. It really works great.

Hi Jack,

Hmm, the world of accurate measurement must be wrong then. :-)

It is correct that into a matched load, it makes little difference - that is not the subject at hand, and as I have said, it has already been demonstrated twice.

To this point I have seen no counter demonstrations, nor counter proposals, nor counter argument (no, Jack, yours is not an argument), nor conflicting bench data. What I have seen are sweeping statements without any supporting evidence. Given the amateur preference for the snuggly comfort of illusion, I suppose none of this will change. Not that I care, it does provide me entertainment (right now in fact) when astonished correspondents post their plight and are offered responses of nostrums and head-bobbing. I would offer that it is a joke that never grows tired - simply because so few would recognize they had a problem in the first place. In fact, this second demonstration arose through the naive investigation of a non-amateur. Too many amateurs consider themselves above such bench activity and too sophisticated to trod that path.

The flip side of the argument (and why it is so painfully ignored) is that reveals that most rigs DO exhibit a Z of nearly 50 Ohms such that this is rarely a problem. It also reveals a shortfall of bench experience in amateur construction. There was a time when many more suffered this because they built their own transmitter instead of passing a credit card across the display case to a sales clerk.

Not unusual since your above deadline for counter demonstrations,
counter proposals, and counter arguments was 66 minutes from the
time you made the original posting. :-)

You are in a room with a 150 ohm (lossless) transmission line coming
through a hole in the wall and with a 50+j0 ohm load in the center of
the room. Are you telling us that the SWR is not (1+|rho|)/(1-|rho|)?
